

where the disease rebounded to equal the high morbidity rates of the last century. Southern and southeastern Europe was mercifully spared these wartime increases, possibly due in part to the fact that it was recovering from high rates during the previous decade when northwestern Europe had been enjoying a moderate decline unattributable to immunization.

The pre-war years had, however, been marked by several features which held an ominous foreboding for the diphtheria situation. The first of these was the obvious prevalence in Europe of a form of diphtheria appreciably more malignant than that which prevailed in the United States. This form had been repeatedly described in England and Germany as well as in other countries. In Germany there had been much speculation about its relationship to coincidental streptococcal infection and even doubts as to the adequacy of diphtheria antitoxin in treatment. The English studies of strains of diphtheria bacilli, distinguishing *gravis*, *mitis* and *intermedius strains*, gave hope of an explanation of the enhanced virulence of the prevailing infections. Although most bacteriologists in this country currently doubt the significance of this differentiation of strains, certain English investigators still attribute significance to it. Regardless of the explanation, there was doubtless a more malignant form of diphtheria in Europe, and one might logically wonder as to the efficacy of immunization in the United States if the more malignant strains were to be introduced.

A second factor that added to the gravity of the pre-war situation in Europe was the lack of immunization. Exact data as to extent of immunization are not available. It is obvious, however, that the procedure had not become an accepted part of the public health program to the same extent as in the United States and Canada, and that

even in those countries such as Denmark, France, and Hungary where it has been used extensively, only a very small segment of the population had been reached. England had hardly been touched whereas Norway was almost completely non-immunized, the only children who had been protected being the rare child immunized by a private physician. The number of these was so small that the Norwegian authorities themselves described the country as completely non-immunized. The low incidence rates, rivalling the lowest state rate in the United States, were attributed to the efficacy of conventional restrictive measures or to other factors that had made control possible without resort to immunization.

A third element of concern was the fact that at the outset of the war, diphtheria prevailed in some parts of central Europe at a higher rate than had been experienced in this country since the preimmunization period. Exact morbidity rates are hard to determine owing to inadequacies of reporting, unknown differences in case fatality rates, and uncertainties as to population, but the data in Table 1 represent adequate approximations. The data show a high rate in central Europe and England, more moderate rates in northwestern Europe, and remarkably low rates in

TABLE 1
Diphtheria Morbidity Rates — 1939
(Per 100,000 Population)

Country	Population *	Cases	Rate
Austria	6,694,782	19,137	285
Denmark	3,835,000	1,106	29
Eire	2,980,000	2,087	70
England and Wales	41,400,000	47,698	115
France	42,000,000	14,019	33

Norway and Sweden. As many of these lower rates had been achieved without resort to immunization, the population represented veritable tinder in which a conflagration might develop if the spark should spread from central Europe.

Such was the situation preceding the wartime explosion of diphtheria in northwestern Europe—a highly susceptible population already threatened on the East by a high incidence of diphtheria, much of which was of a virulent form. England alone adopted an energetic and highly successful control program through extensive immunization as a part of its civilian defense program. In 1939 France had ordered universal childhood immunization effective June 1, 1940, but France's defeat that spring had precluded enforcement of the program. Nazi conquest of Norway, Denmark, Belgium, and the Netherlands not only precluded active control measures but may even have precipitated the diphtheria outbreak through enforced malnutrition, crowding, and lack of medical supplies and services. The extent of the outbreak of diphtheria is shown in Table 2. It will be noted that Norway and the Netherlands, countries which felt the weight of the oppressor's yoke most severely, suffered the most. The disease began to increase rapidly during 1941, reaching its peak during the winter of 1943-1944. During the spring of 1944 the weekly incidence in the Netherlands was almost twice the pre-war yearly incidence. Denmark, which was possibly the best

immunized country of this area, felt the increase somewhat later than its neighbors and never suffered to the same degree. In Sweden the increase began in 1942 and was of somewhat less serious proportions. Accurate data for many of these countries for 1944 will probably never be available. In 1945 and 1946 the disease has continued throughout northwestern Europe at a high rate but very much below the 1943-1944 peak. Table 3 shows sample comparative data.

The wartime data of the British Isles present an interesting contrast to the continental experience. Table 4 shows the incidence in war-congested England and Wales on the one hand, and in neutral Eire on the other. The former, facing the obvious risk of increasing diphtheria—a risk accentuated by displacement of the population and crowding in air-raid shelters—provided for extensive immunization; the latter did little to protect itself against an in-

crease. Whereas Eire experienced an increase from less than 2,000 cases in 1941 to over 5,000 in 1944, England and Wales enjoyed a decline to the lowest level ever recorded, a rate of decline comparable in magnitude with that of the United States during the same period (Table 4). The English data are of special significance, for this country was the only part of northwestern Europe that weathered the storm with a significant decrease in diphtheria. May it not have been more than mere coincidence that it was also the only country that increased its immunization program to a point comparable with that of the United States and Canada? The data strongly suggest that immunization is actually effective in guarding against whatever strains of infection may have been operative in Europe during the war period.

* Source of data: *Epidemiological Information Bulletin*, United Nations Relief and Rehabilitation Administration. 1:241-246 (Mar. 15), 1945.

The explanation for the dramatic outbreak in northwestern Europe is not clear. Some persons have talked freely of strains of diphtheria bacilli of increased virulence. Unfortunately for this hypothesis, no one has demonstrated strains that differ in virulence from those that prevailed in this area before the war. The usual number of *gravis* strains are still being reported in England but their significance is still problematical. Furthermore, the disease as it was seen in Norway and the Netherlands was not more severe than in for-

mer years; on the contrary, the only comforting aspect of the outbreak was the fact that the prevailing form was relatively mild even though there was a shift upward in the age distribution. It is my personal belief that the most probable explanation is to be found in factors of crowding, impaired nutrition, and lack of immunization and medical care. If the level of resistance may be depressed by faulty nutrition, persons who might normally have resisted infection or become mere carriers would have developed clinically recognizable or subclinical attacks. Doull and Lara some years ago showed that, given equal opportunities for exposing other persons, cases have an infection potential some ten times that of the carrier. A slight shift in the balance of community resistance might thus precipitate a wave of infection and this wave be augmented by increased opportunities for exposure of others owing to the overcrowding incidental to wartime conditions. I cannot escape the suspicion that these demonstrable secondary factors were of greater significance than the presence of some hypothetical and still undemonstrated enhanced virulence of the prevailing strain of infection. If this be the explanation, there is little reason to fear that other countries will be menaced by this diphtheria wave. So far, at least, we have seen no evidence of such menace, and if the experience of England is any guide, we have seen evidence that immunization in its present form is an adequate measure of protection.

Coincident with these significant phenomena in western Europe there has been an equally interesting shift in the diphtheria trend in the United States and Canada. Both countries had experienced a pre-war decline in diphtheria far greater than had been observed in any other part of the world. Beginning in 1923 the United States had enjoyed an almost precipitous drop

to previously unachieved minima. Except for slight variations and momentary upsurges, this had been a constant decline, paralleling the increasing acceptance of immunization. The drop was most marked in the northern half of the country which had formerly experienced higher rates than had the South. Today by way of contrast the diphtheria rate is very significantly higher in the South, whereas the north-eastern section of the country, which for years had experienced the highest rates, has today the lowest. It is hard for me to escape the belief that this difference is not significantly related to the extent of immunization.

During the last few years, however, there has been in some places an upsurge in diphtheria that has caused some concern and even precipitated fears lest military forces returning from Europe might be introducing more virulent strains of infection. One of the earliest and most disconcerting evidences of a rise in the western hemisphere was the outbreak in Halifax in 1940-1943. While it is true that *gravis* strains were isolated here, that the age distribution tended toward older age groups, and that many of the cases were quite

severe, yet there was nothing to cast serious doubt on the efficacy of immunization or to suggest that the apparent severity of the infection was associated with the introduction of more virulent strains than already existed in North America.

In the United States the increase has not been marked by particular episodes like that in Halifax. On the contrary it has been more general over certain areas. Table 5 based on data for 52 weeks as published in the *Public Health Reports*, shows the changes in incidence over the past few years. The year 1943 represented a minimum after which there was a sharp rise in 1944 and 1945. During the first half of 1946, the incidence was higher than for the corresponding period of any of the previous three years, but during the summer the trend shifted and the weekly rates for the current fall are strikingly below those of a year ago (Table 6). The rise in 1944 and 1945 was due principally to marked increases in incidence in the South and Southwest. The present decline is marked by an incidence below that which prevailed prior to the 1944 and 1945 rise in those areas. At the same time, however, we

40	432	517	550	387	409	514	351

are seeing a slight increase in rates in the North, a rise that is more than offset by the decline in the South.

These changes in incidence do not suggest changes in the character of diphtheria, nor are they suggestive of the introduction of strains of enhanced virulence. On the contrary, they probably represent the normal fluctuation in the incidence of the residual diphtheria. We have enjoyed declines in rates for so long that many persons seem to have forgotten that in the preimmunization era, diphtheria showed periodic fluctuations in incidence, with peaks spaced three to five years apart. Careful study of the declining morbidity rates reveals that the rate of decline was not constant; on the contrary it showed variations comparable to the previous periodic changes in incidence. These fluctuations were not constant throughout the nation. It is logical to believe, therefore, that the episodes of the past three years do not imply any profound or even significant change in the diphtheria problem, but rather that they represent the normal fluctuations in incidence that were formerly masked by the precipitous decline of the disease. There is no evidence that they are due to defects in immunization. On the contrary, the increases were greatest in those areas where diphtheria was already highest. The best immunized communities with the lowest rates experienced the smallest rise in incidence. Furthermore, so far as I am aware,

nowhere has there been a sharp upsurge attended by enhanced severity of the infection and isolation of an especially virulent strain of organisms.

SUMMARY

From the foregoing it is apparent that the past five years have witnessed an actual increase in the incidence of diphtheria. Although occurring throughout the world, the only significant episode has been that of northwestern Europe where an amazingly high rate occurred in certain occupied areas, with appreciably smaller increases in neutral countries. There is reason to believe that this was attributable to secondary epidemiological factors rather than the appearance of new virulent strains, and that it was controllable by vigorous programs of immunization. The rise in the United States during the past two years is probably an expression of the normal periodic fluctuations in incidence, fluctuations that have heretofore been largely obscured by the rapid increase in the proportion of the population that was being immunized. That this is nothing more than a transient rise is suggested by the fact that the disease is again declining rapidly in those parts of the country chiefly responsible for the rise.

There is no evidence that especially virulent strains have been introduced from Europe or that immunization is not effective against all prevailing strains.

Rhus Dermatitis as a Public Health and Health Education Problem

C. E. TURNER, Ed.M., Sc.D., DR.P.H., F.A.P.H.A.

PUBLIC health authorities can and should secure the elimination of most of the Rhus poisoning in the United States within the next few years. The effectiveness of two new chemical herbicides, ammonium sulfamate and 2-4 dichlorophenoxyacetic acid, which have just come into use, provide the first really promising solution of this public health problem. By means of community organization through health education, the eradication of the plant in frequented areas is now readily possible.

EXTENT OF RHUS POISONING

Rhus poisoning has received only minor attention from public health authorities, yet the U.S.P.H.S. study on the illnesses of 38,544 people shows a rate of 2.5 cases per 1,000 people annually.¹ Seventeen and seven-tenths per cent were bed cases and were in bed 3.6 days on the average. The mean days of disability per total case were 1.7; per bed case they were 4.9. The average total duration of the symptoms was ten days. Cases appeared in every part of the country, the crude case rate per 1,000 being 2.3 in the Northeast, 1.5 in the North Central states, 2.5 in the South, and 4.6 in the West. The numbers are too small to make these figures a reliable index of frequency, but they do show the national distribution of the plant. Of the cases 71.9 per cent were attended medically, the average number of calls per attended case being 1.93.

National estimates using these figures as a basis indicate 350,000 cases per

year, with approximately 600,000 days of lost time and 465,000 medical visits. Most cases are uncomplicated, but abscesses, enlarged glands, fever and septicemia from a secondary infection occasionally occur.¹⁵

The incidence of Rhus poisoning runs much higher among youth in localities where the plant is profusely distributed. In one student body where data were available upon about 5,000 students for a 2 year period, 6.5 students per 1,000 were hospitalized yearly for an average of 6.9 days each, representing a per capita cost of 56 cents for each student in the student body. In addition, 41 students per 1,000 sought medical aid but did not require hospitalization.² Many others treated themselves.

POPULAR MISCONCEPTIONS

There are three widespread misunderstandings:

1. *The public thinks of poisonous forms of ivy, or oak or sumac.*

Really, of course, the plants are of only a single genus, *Rhus* or *Toxicodendron*, and perhaps of only one species. In the past over fifty species have appeared in the literature under the genus *Rhus*. They have now been given a new classification accepted by the U. S. Herbarium in Washington, D. C., under the genus name *Toxicodendron*.³ The species listed in this classification are: (1) *Toxicodendron toxicodendron* (the former *Rhus toxicodendron* or *Rhus quercifolia*), (2) *Toxicodendron radicans* (eastern ivy), (3) *Toxicodendron diversilobum* (western poison oak, *Rhus lobata* or *Rhus*

diversiloba), (4) *Toxicodendron vernix* (swamp sumac, *Rhus vernix*, *Rhus venenata*).

The first three species were recently brought from different parts of the United States to Texas by Shelmire.⁴ Having grown side by side they were so similar as to suggest that they are a single species with rather consistent geographic variations. Chemical and biological research indicates that the same chemical substance (urushiol) is the toxic substance in all of these plants.⁵

2. *It is generally believed that some individuals are so sensitive that they are poisoned if they "go anywhere near the plants."*

Studies of urushiol show it to be a dializable but nonvolatile oily resin. Soot particles in the smoke from burning plants carry enough of the substance to produce poisoning,^{6, 7, 15} but otherwise it is not air-borne, although statements to that effect have appeared in the literature until recently.¹⁶

How is it then that it has been practically impossible for highly susceptible persons to avoid repeated poisonings? The answer lies in the fact that poisoning occurs by indirect as well as direct contact, and as little as 0.001 mg. will cause dermatitis in such persons.⁸ The poison is transmitted indirectly by cats, dogs, horses, and other animals which walk over the plants, and also by clothing, tools, soil, and other surfaces. It is quite possible that insects may carry enough poison from broken leaves to cause dermatitis.⁵ Naturally persons say they can get poisoned "without going outside the house," or in various apparently strange ways. This situation is similar to that which existed a century ago when even the profession regarded typhoid fever as air-borne.

The difficulty of avoiding poisoning is increased by the fact that the plant is pleomorphic. Poison oak may be a

slender, inconspicuous vine bearing leaves some distance apart, or a more conspicuous vine, or an upright stock growing out of the ground, or a bush running to almost tree-like proportions. The leaves vary in shape and the plant is often partly hidden by other plants among which it is growing. Interviews with college students who have grown up in areas where the plants are plentiful show that a large percentage of them do not recognize the plant in its various forms.

The plants are spread not only by underground roots and the fruit which is dropped to the ground, but also by seeds in the droppings of the birds which have eaten the berries.⁹ Thus it appears in all sorts of places, in fields, in woods, in parks, in gardens and by the roadside. The writer has photographed it growing through cracks in the pavement.

It is thus the plant's toxicity, pleomorphism, and ubiquity which make poisoning extremely difficult to avoid by the highly susceptible.

3. *There is widespread confusion as to the nature of susceptibility and "immunity."*

The idea that some persons have a true, natural immunity is wrong. It is believed that we are dealing with allergy and desensitization rather than with a true immunity, natural or acquired.

"All observers believe that the typical dermatitis is the result of contact after previous exposure and sensitization to the active substance in the plants. Infants, adults, and certain animals have been sensitized with the plant extracts or with urushiol. There is also some evidence that this sensitization resulting from either experimental or natural contact diminishes in intensity if not maintained by repeated exposure."⁵

Some persons have a marked resistance to the action of the poison,

although their skin becomes inflamed upon prolonged exposure to urushiol. Such a person may have had repeated contact with the plant without symptoms, only to develop a severe poisoning upon a subsequent exposure.¹⁰ Medical authorities have warned against the practice of chewing leaves in an attempt to produce immunity, because the practice does not give protection but often produces symptoms.

PREVENTIVE PROCEDURES

Attempts to teach children and the general public to recognize and avoid these plants could be carried farther but to date, as we have seen, it has been relatively ineffective. Prevention or early treatment by prolonged washing with alkaline soap or a chemical agent for removing the poisoning is effective only if undertaken "within a few minutes after contact."⁹ The victims often do not know when they have been exposed, and urushiol on the skin is invisible. After the area reddens and begins to itch "any treatment now known will serve only to make the patient more comfortable; it will do little to hasten recovery," according to some authorities.⁹ However, the Boy Scouts of America report good results from experience in many parts of the country in treating vesicular eruptions with 10 per cent tannic acid solution as recommended by Schwartz and Warren.¹⁷ Many people claim great benefit from one or another of the many suggested remedies, but none appears consistently beneficial for different individuals or even for the same individual.¹⁵ Clothing or tools can be decontaminated by immersing them for 15 or 20 minutes in 1 per cent solution of calcium hypochlorite, but the practice is little followed.

The failure of these hygienic measures has led to widespread attempts at desensitization, but this too has proved far from satisfactory. "The Council of

Pharmacy and Chemistry admitted rhus preparations to *New and Nonofficial Remedies* in 1926, but since then there has been a growing controversy regarding the real value of rhus preparations."⁵ There is some evidence that the ingestion of extracts over a period of 6 weeks or less can produce temporary desensitization if the doses are so large as to cause rashes and gastrointestinal symptoms, but the Council states⁵ that "there is no controlled statistical evidence that the daily ingestion of small amounts of extract over a long period will modify the dermal test or give protection, and the ingestion of large doses within a period of a few months is still experimental." Moreover, this intensive treatment is probably unsafe except under experienced supervision.

There is some clinical evidence that intramuscular inoculation has conferred temporary resistance, but the patch test was not modified in these studies and the inoculated subjects were not vigorously exposed to poison after the inoculation.⁵

Preventive treatment with ivy extracts thus seems far from satisfactory. The effectiveness is uncertain and the process is uncomfortable as well as expensive for the individual. Even if it were effective, the preventive treatment would have to be continued year after year because desensitization is only temporary, when it does occur.

Our unsatisfactory experience in preventive hygiene and preventive medicine turns our attention to environmental control, where we now have for the first time some promise of success. Earlier attempts to kill the plants or dig them out were unsuccessful but the new chemicals kill the plants, root and all. You may feel that it is hopeless to attempt to eradicate the plant immediately over millions of acres of land. Complete eradication at once is not necessary. The poison is not air-borne

and the cheapness of some of the chemical herbicides makes it possible to eradicate the plant near dwellings and in other frequented areas like roadways, parks, and cultivated lands, even if the growth is fairly extensive.

CHEMICAL AGENTS

With ammonium sulfamate or "Ammate" and 2,4-dichlorophenoxyacetic acid, or 2,4-D, commercial companies engaged in weed control are now ready to guarantee the complete eradication of poison ivy or poison oak.

Ammonium sulfamate is not explosive or poisonous to animals, and it is now available in a form which is not corrosive to metals. It is highly effective and can be used later in the season than 2,4-D. It kills other plants. Grass tops are killed but the grass will usually come up from the roots. It is rather expensive, costing about 30 cents a pound at retail and 15 cents a pound in larger quantities. About one pound is needed in making a gallon of spray. A heavy growth of poison ivy or poison oak would require from 100 to 300 gallons of spray per acre.

2,4-D is a hormone-like chemical which in small quantities stimulates growth but kills active broad-leaved plants completely when applied to the leaves in greater concentration. Some respraying of missed plants after a month, and a yearly spring check-up will be needed. But when the plant is eradicated in frequented areas, the seeding of new plants will be limited.

The early research on this substance was by Pokorney¹⁸ and by Zimmerman and Hitchcock,¹² in 1941 and 1942. The methods of using it for killing plants were developed by Jones,¹⁹ Mitchell and Hamner,¹³ and others. Wide uses are being found for its weed-killing action.¹⁰ It seems likely to prove of public health significance in the elimination of ragweed as well as poison ivy. Ragweed is among the more sensitive of the

common weeds and considerable success has been achieved in preventing pollen formation by the use of low dilution of 2,4-D as a water spray and also in the form of a fog.¹⁴

2,4-D is relatively inexpensive. The spray can be made for 8' to 12 cents per gallon in small quantity and for as little as \$3 to \$4 per 100 gallons. It is not a fire hazard nor is it corrosive to metals or irritating to the skin or poisonous to man or other animals.¹¹ It does not kill grass in the concentration used but it does kill many broad-leaved plants besides poison ivy. These qualities make 2,4-D more practical than ammate for use in large areas.

Many chemical companies manufacture 2,4-D compounds under various trade names. These weed killers vary in price, in concentration, and in the nature of the chemical compound, which may be the dichlorophenoxyacetic acid as such or the ammonium salt, the sodium salt, the triethanolamine salt, or the methyl, ethyl, or butyl ester. We have little data on their relative effectiveness. 2,4-D is most effective on poison ivy around the end of the growing season. Moist soil and sunlight seem to add to its effectiveness. It always acts slowly, requiring about a month to produce killing action.¹¹

The following precautions should be advocated in advising the use of 2,4-D:

1. Be sure the chemical is well mixed in the correct concentration.

2. Spray when the leaves are well developed, giving a large surface. (2,4-D is not effective late in the season when the plant has become dormant.)

3. Spray the whole plant and cover the leaf surfaces as completely as possible, but be careful that the drift of the spray does not wet flowering plants or fruit trees. (Neither moisture on the leaves, nor rain four or more hours after spraying will prevent the killing action of the spray.)

4. If a few plants have survived, kill them by spraying a second time in three or four weeks.

5. Examine the area the next spring and kill any new plants which may have come up from seed.

6. Clean spraying equipment thoroughly before using other sprays on cultivated plants.

GETTING RESULTS

Eradicating rhus plants with 2,4-D is not a completely simple and foolproof procedure. Obvious difficulties appear when any one of the above directions is not carried out correctly. But real progress can be made through community organization and health education.

An effective community organization was developed in Berkeley, Calif., in the spring of 1946, thanks to an alert Chief of the Park Division, Charles Cresswell; a progressive Health Officer, Dr. Frank Kelley; and an interest on the part of university personnel. It showed clearly that community interest and educational activities can be made effective.

The county medical society and the local dental association joined the project at the beginning. A demonstration of killing poison oak with 2,4-D was carried out on the university campus, the success of which was recorded in still and in moving pictures. The student body put on an educational program of its own, as did the public schools. Twenty-five thousand "stuffers" were sent to citizens with monthly bills from the city and from public utilities. The press, the local radio station, the Boy Scouts, the service clubs, the women's clubs, and commercial interests all participated. As a result an extensive spraying program got under way in local and regional parks, on university grounds, along the roadsides, and on the private property of many scores of individual citizens. There is an ordinance providing that the city can kill noxious weeds on privately owned land and charge the cost to the property owner. This may prove valuable if some citizens

fail to act under the stimulus of education.

FUTURE PROGRESS

Facts and experience now available show that plant eradication is a practical means of attacking the problem of rhus dermatitis. We still need studies on the relative effectiveness of the different commercial products and the best methods of using them. A study should be made to show how rapidly and to what extent urushiol disappears from the resin cells or resin canals of the bark, roots, stems, and leaves after the plant has been killed. It loses its toxicity upon oxidation and the plant contains an enzyme, laccase, which oxidizes the poison when the plant is injured and its juices exposed to air.⁵ Preliminary tests have indicated that the dry, dead plants are much less dangerous than the live plants.

These studies and others will be forthcoming from commercial agencies and from governmental agencies in agriculture and in health. Patterns for community organization need further development. One national agency which is considering ways of effective action and which could render a most important service is the Boy Scouts of America. Park departments and recreation agencies can be counted on for effective action as can the wide variety of agencies with civic interests. We can prevent a quarter million cases of ivy poisoning a year—some of them very serious—if we use the necessary leadership and effort.

SUMMARY AND CONCLUSIONS

1. Preventive hygiene and attempted desensitization have not proved effective in preventing rhus dermatitis.

2. Eradicating the plants in frequented areas by means of 2,4-D or ammonium sulfamate provides a practical means of prevention.

3. Effective community organization for

health education in the eradication of poison oak has been demonstrated.

4. Health department leadership and the coöperative efforts of community agencies can reduce the now prevalent dermatitis to a relatively rare illness.

The Present Status of the Control of Air-borne Infections*

FOR several decades prior to 1934 it was generally believed that the acute respiratory and contagious diseases were spread largely by contact.^{1, 2} Since that time, however, it has been clearly established that the air of enclosed spaces may become heavily contaminated with a variety of pathogenic microorganisms, and that certain specific infections may be transmitted to experimental animals by the aerial route.³⁻¹¹ These observations have led many students to question the predominant rôle of contact in the spread of infection and to undertake investigations in the attempt to control disease by the application of engineering methods to the disinfection of air (sanitary ventilation) and to the prevention of aerial contamination (dust suppression).¹²⁻¹⁷

Numerous reviews of the subject have been published in scientific journals,¹⁸⁻²⁵ and optimistic but frequently uncritical stories of the potentialities of the field have reached the commercial and lay press. The purpose of this report is not primarily to present an additional review of recent progress but rather to give a critical evaluation of the present status and limitations of existing methods. Such an evaluation depends not only upon the engineering aspects of air sanitation but also on the epidemiological evidence supporting the concept of air-borne infection.

DEFINITION OF TERMS

Some confusion has arisen in the discussion of the subject because of the lack of a clear definition of terms. In the present report, the term *sanitary ventilation* will be used to connote the disinfection of air by actual ventilation or its equivalent through such methods as ultra-violet irradiation or germicidal vapors. The term *air sanitation* will include all types of applications of engineering methods to the prevention and removal of air contaminants such as dust, bacteria, and other noxious agents.

There is need also for a clarification of the term "air-borne infection." This expression has been applied to a number of respiratory and contagious diseases and to secondary skin and wound infections which are known to be spread, at least in part, by contact. A practical delineation of meaning of the terms "contact" and "air-borne" is desirable.

The routes by which these types of infectious agents travel from one individual to another may be classified under four general headings:

1. *Contact*, transmission directly, as in kissing, or indirectly by contaminated hands, toys, surgical instruments, or other material objects.

2. *Droplets*, transmission directly by projection onto the conjunctivae, mouth, skin, or open wounds.

3. *Droplet nuclei*, transmission indirectly by inhalation of the small residues which result from evaporation of droplets, and which may remain suspended in the air of enclosed spaces for long periods of time.

4. *Dust*, transmission indirectly by inhalation or settling of larger particles

* Report of the Subcommittee for the Evaluation of Methods to Control Air-borne Infections, of the Committee on Research and Standards.

Organized 1945. First report: Presented before the Epidemiology Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 14, 1946.

which arise from secondary reservoirs of infection on floors, clothes, or bedding, and which remain suspended in air for short periods of time.

The spread of infection by contact or by droplets is subject to control by methods which influence human behavior or restrict individual activity, such as the promotion of personal hygiene, isolation, quarantine, aseptic techniques, and barrier nursing. The spread of infection by droplet nuclei and dust is an environmental problem amenable to attack by methods of air sanitation.

Confusion arises in regard to the rôle which should be ascribed to droplets. Although these actually travel short distances through the air, it has been traditional to consider them as an intrinsic aspect of contact infection.¹ Furthermore, droplets are not affected appreciably by any of the devices of sanitary ventilation which have yet been developed. In the present discussion, therefore, the term "contact" will be considered to include droplets, and the term "air-borne" will be restricted to transmission of infection by droplet nuclei and dust.

GENERAL CONSIDERATIONS

On the basis of this definition, the technical aspects of the problem will be limited to an evaluation of the present status of the devices of air sanitation. Broader aspects of the problem must also be considered. It is necessary to know the true relative importance of air-borne and contact spread of disease under a wide variety of environmental conditions. The disinfection of air can be of practical value only in situations where the aerial route of infection is important in the mode of transmission.

Other considerations beyond the scope of the present report cannot be wholly ignored. The methods of air sanitation are in competition with other control measures. Aseptic techniques

and isolation precautions are well established procedures in operating rooms and hospital wards. Immunization has been highly successful in certain specific diseases. Chemoprophylaxis may have limited applications. Therapy with sulfonamide drugs and antibiotics reduces in large measure the serious consequences of many bacterial infections. The future of air sanitation in the prevention of disease depends upon the demonstration of its practical superiority to other approaches to the problem.

PRESENT STATUS OF CONTROL METHODS

The methods of controlling air-borne infection have developed in four principal directions: (1) mechanical ventilation, (2) ultra-violet irradiation, (3) disinfectant vapors, and (4) dust suppression. In developing these procedures, the usual criteria of effectiveness have been the reduction: (1) of test organisms added to air, (2) of the total bacterial count of air, (3) of certain microorganisms usually found in the nasopharyngeal tract, and (4) of certain specific pathogens such as beta hemolytic streptococci or influenza virus A. While bacteriological criteria have been of great practical value in the development of the procedures, they are insufficient. The final criterion of effectiveness must be the demonstration of a significant reduction in the incidence of disease in well controlled studies in human populations living under natural conditions.

Ventilation — Simple ventilation by means of open windows has been a common hygienic practice for many years. Its use has been traditional in military barracks where it has been notable for its unpopularity among troops and the difficulty of its consistent enforcement. British workers have recently reëmphasized the desirability of open window ventilation in contagious disease wards.²⁶ Although it

is probable that such measures may have considerable effect in reducing the bacterial contamination of the air, they are obviously expedients of limited value which are subject to variable climatic conditions and which may cause extreme discomfort.

Under certain specialized conditions, the control of air currents and air conditioning either alone or in conjunction with physical barriers and other procedures has been applied with somewhat variable success to the control of cross-infections in surgical dressing rooms,²⁷ in pediatric and premature infant wards,^{15, 28-31} and in animal colonies and laboratories of research institutions.^{32, 33} Under more general conditions, however, the purification of air through washing, filtration, and forced ventilation is a relatively inefficient method of reducing the bacterial content of air in occupied spaces.³⁴ Normal human activity maintains a continuous source of contamination which is difficult to eliminate by economical rates of air dilution. Nevertheless, a careful consideration of temperature, relative humidity, air currents, and rates of introduction of outside or recirculated air is fundamental to the effective application of the other more efficient means of air disinfection.

Ultra-violet irradiation—The bactericidal action of ultra-violet light is well established and accurately defined.^{24, 35-40} The effectiveness decreases rapidly with increasing relative humidities above 55 or 60 per cent. The rays are more efficient against small particles, such as droplet nuclei, than large particles, such as dust and lint, in which microorganisms may have a protective coating impermeable to the bactericidal rays. Since germicidal intensities are damaging to the human skin and conjunctivae, radiation must be restricted to the upper air or to carefully placed light screens or barriers at the entrance to rooms or to isolation

cubicles.⁴¹ Under standardized test conditions practical intensities of ultra-violet light have been shown to have a marked effect in lowering the bacterial contamination of the air equivalent to 100 or more air changes an hour.⁴² Under field conditions, this degree of effectiveness is not always reached; but, nevertheless, a pronounced effect may be induced.

The development of the low pressure mercury vapor tube, of carefully designed fixtures, and of accurate photometers to measure intensity makes possible the safe and reasonably economical installation of ultra-violet lights in a variety of circumstances. Each particular environmental situation, however, presents a specialized problem which requires the expert consultation and continued supervision of ventilation and irradiation engineers.²⁴

The use of ultra-violet irradiation in the control of infection has been undertaken in operating rooms, in pediatric and contagious disease wards, in schools, in military barracks, and in children's institutions. The most impressive results have been reported from operating rooms.^{14, 43} The residual contamination of the air which remains even after the most rigid aseptic precautions can be greatly reduced by intensive irradiation. Reports indicate substantial reductions in the incidence of secondary infections of originally clean operative wounds. To achieve such results, with early installations it appeared to be necessary to take extreme precautions to protect the operating personnel; but improved designs have made such precautions unnecessary.⁴³

Ultra-violet irradiation of the upper air and the use of light screens in front of cubicles and in entryways to pediatric and contagious disease wards have been employed in a number of institutions. Rather dramatic results have been reported by a number of workers in carefully controlled experiments.^{15, 31, 44}

Negative results have been reported by others.⁴⁵⁻⁴⁷ It is difficult to evaluate these because of (1) inadequate information regarding the efficiency of the installations; (2) the lack of a sufficient number of controlled observations; and (3) the problem of distinguishing which infections were air-borne and which may have resulted from contact.

Irradiation of the upper air of schoolrooms in Swarthmore and Germantown, Pa., has been carried out continuously since 1937.^{13, 48, 49} During the early part of this period, two epidemics of measles were apparently prevented among children in the primary grades whose rooms were irradiated, although large epidemics occurred among the less susceptible children in the secondary grades whose rooms were not irradiated. Beneficial effects in the reduction of the incidence of chicken pox have also been reported, although the procedure was less successful in controlling an epidemic of mumps which occurred in the early fall of 1941 when relative humidities were high.

The application of ultra-violet rays in the schoolrooms provides a very valuable approach to studying the importance of air-borne spread of infection, but the extent to which this procedure should be applied generally is uncertain. More extensive studies, now in progress, should add materially to our understanding of the problem.

Irradiation of the upper air, of the corridors, and of the floors of the naval barracks at Camp Sampson, New York, was investigated during the winter of 1943-1944.⁵⁰ In one group which received high intensity irradiation, there was a 25 per cent lower incidence of "respiratory admissions" than among comparable groups of controls. These studies have been continued and extended, but results have not yet been reported.

One study of ultra-violet irradiation has been conducted in the restricted

population of an institution for delinquent adolescents in Washington, D.C.⁵¹ No reduction in the incidence of respiratory disease was demonstrable over a period of two years, but the total incidence rates were generally so low that a measurable effect could hardly have been anticipated.

These studies suggest that ultra-violet irradiation has its most direct application in specialized situations where the incidence of cross-infection is high, where the consequences of such infections are serious, and where the population is strictly regimented, as in operating rooms, pediatric hospitals, and analogous situations. However, the evidence, at present available, is insufficient to warrant the use of ultra-violet lights in more general population groups except in well controlled research studies.

Disinfectant vapors—Numerous vapors have been shown under experimental conditions to have a powerful bactericidal effect in air. Among these are hypochlorous acid gas,⁵² lactic acid,⁵³ iodine,⁵⁴ and certain glycols.^{16, 21, 55, 56} Triethylene glycol appears to be the most adaptable for general use because of its high bactericidal potency, its reasonable cost, and its freedom from odors, toxicity, and corrosiveness to metal surfaces. The mechanism of action of this vapor has been carefully studied.⁵⁷ Its bactericidal effect depends upon its relative saturation in the air rather than upon the total concentration. Under laboratory conditions the vapor is most effective at relative humidities between 30 and 55 per cent. On hospital wards, however, effective bactericidal action was obtained at relative humidities as low as 18 per cent.⁵⁸ Methods for vaporizing triethylene glycol into the air and for maintaining its relative saturation at a constant level have been developed on an experimental basis and give promise for being standardized for practical purposes.^{57, 59}

Glycol vapors are more effective

against small particles or droplet nuclei in the atmosphere than they are against larger dust particles.⁶⁰ The most effective reduction in bacterial contamination has been observed when glycol vapors have been used in conjunction with dust suppressive measures.⁶¹

Studies of the effect of glycol vapors in the control of respiratory infections have been conducted in isolation wards of army hospitals,^{61, 62} in barracks,^{63, 64} and in a home for crippled children.⁶⁵ Most of these studies, however, were undertaken prior to the development of accurately standardized methods for maintaining the concentration of vapors at a bactericidal level. Observations have not been continued for sufficient periods nor have controls been adequate to provide conclusive evidence.

The use of glycols has one distinct advantage over ultra-violet irradiation in that the vapor may permeate all parts of the room and is not restricted to the upper air. There are, however, a number of technical problems which remain to be solved, among which are practical methods of vaporization and maintenance of an adequate and even distribution of bactericidal concentrations of vapor.⁶⁶

Dust suppression—The application of light paraffin or spindle oil to the floors of military barracks and army hospital wards has been shown to be a simple and effective procedure for laying dust and thereby reducing the bacterial contamination of the air resulting from sweeping or other activity.⁶⁷ A saturation dose of oil to unvarnished soft wood floors remains effective for a period of three months or longer. More frequent treatments may be necessary for hardwood floors. The procedure cannot be used for concrete, linoleum, or waxed surfaces, but the daily use of oiled sawdust or oiled mops during sweeping is quite effective.

Numerous methods have been developed for the oil impregnation of

blankets, bedding, and certain types of clothing.⁶⁸⁻⁷³ Treated fabrics show marked dust and bacteria holding properties. Recently, a simple method has been developed which can be applied as a routine procedure in any modern well equipped laundry.⁷² A stable oil in water emulsion, made with a neutral detergent, Triton N.E., is added at the time of the final rinse in the laundering process. After such treatment, woollen fabrics such as blankets retain their dust and bacteria holding properties for many months, even after subsequent washing.

A few controlled studies of the effect of dust suppressive measures on the incidence of respiratory disease have been carried out. A marked reduction in the incidence of beta hemolytic streptococcal cross-infections was observed in one measles ward compared with an untreated adjacent ward to which alternate cases were admitted.¹⁷ At Fort Bragg, N. C., during the winter of 1944-1945, four battalions of recruits (2,000-4,000 men) were observed over a period of 6 months.⁷⁴ In the barracks of alternate batteries floors and blankets, sheets, pillow cases, and mattress covers were oil-treated. During November and December when respiratory diseases were endemic, somewhat lower rates were observed in the treated groups. During the 4 month period from January to April, however, when undifferentiated acute respiratory disease was epidemic, no difference in incidence between test and control groups was observed. In this experiment the incidence of beta hemolytic streptococcal infections was too low to test the effect of the procedures on this group of diseases.

The oiling of floors and bedding has been developed to the stage of practical application. These methods are particularly useful for the maintenance of general cleanliness; they result in a marked reduction in the degree of bacterial contamination of the air; they

can be recommended for use as general hygienic measures; but there is insufficient evidence at the present time to establish their value in the control of respiratory diseases.

EPIDEMIOLOGICAL CONSIDERATIONS

The limiting factor in the evaluation of the effectiveness of measures to control air-borne infection is the lack of sufficiently extensive experimental and epidemiological observations to determine the true relative importance of this mode of spread. The available data can be grouped under three broad headings: (1) Experimental demonstrations of air-borne infection, (2) descriptive field observations, and (3) controlled studies. Each of these will be discussed briefly.

Experimental demonstrations—A limited number of infections have been transmitted to animals and to man by the air-borne route under strictly controlled conditions. Examples of these experiments are the transmission of tuberculosis to rabbits,¹¹ of influenza A and B to mice and ferrets,^{4, 75-77} of canine distemper to ferrets and dogs,⁷⁸ and of poliomyelitis to monkeys.⁷⁹ During the direct inoculation of volunteers with the viruses of measles⁸⁰ and atypical pneumonia,⁸¹ cross-infections were observed among uninoculated individuals under conditions which strongly suggested the air-borne route of infection. These observations clearly demonstrate that certain infectious agents may be acquired by inhalation in sufficient doses to produce clinical disease.

Descriptive field observations — In most epidemics of respiratory and contagious diseases which occur in nature, it is not possible to distinguish between contact, droplets, and air-borne methods of transmission. In certain laboratory epidemics, however, conditions have precluded any other means of spread than the air. This is particularly true for psittacosis⁸² and Q fever,^{83, 84} and it

also probably applies to a number of bacterial, rickettsial, and viral infections which are known to be peculiarly dangerous to laboratory workers or which are difficult to exclude from animal colonies.

The occurrence of cross-infections in communicable disease wards and of secondary infections in clean surgical wounds was formerly considered to be *a priori* evidence of faulty technique. The consistency with which a residual number of such infections have continued to occur, however, in spite of the most rigid precautions favors the concept of air-borne spread.²² The demonstration of large secondary reservoirs of beta hemolytic streptococci, of diphtheria bacilli, of staphylococci and other pus forming organisms in the environment, and in the dust surrounding patients also supports strongly the possibility of air-borne transmission. It should be emphasized, however, that under such conditions the likelihood of contact infection is also greatly increased, and it is difficult to ascertain the relative importance of these two modes of spread.

Controlled studies—As yet, an insufficient number of adequately controlled studies have been reported upon which to base any general conclusions. Only certain tentative indications may be outlined at the present time. For example, the reduction in the incidence of operative wound infections and of cross-infections in pediatric and communicable disease wards and of measles in certain schools by the use of ultra-violet irradiation suggests that air-borne transmission, particularly by droplet nuclei, played an important rôle under the particular conditions of those experiments. Similarly it is reasonable to conclude that droplet nuclei were of some importance in the transmission of acute respiratory diseases in the naval barracks at Camp Sampson. On the other hand, an equally logical conclusion can be drawn

from the studies at Fort Bragg that dust was an unimportant factor in the spread of the epidemic acute respiratory disease prevalent at that post. Furthermore, the spectacular results which followed the introduction of aseptic surgery and isolation techniques thirty to fifty years ago indicate the importance of contact infection in operating rooms and hospital wards.

Conclusive evidence is not available at present that the air-borne mode of transmission of infection is predominant for any particular disease. There is no justification for the conclusion that the traditional methods of controlling contact infection can be ignored or relaxed.

There is need for more precise knowledge regarding the epidemiology of acute infectious diseases in crowded populations. For example, recruits in military training camps generally experience an unusually high incidence of acute respiratory disease and atypical pneumonia during winter months.⁸⁵ During the war years, devastating epidemics of beta hemolytic streptococcal infections and acute rheumatic fever occurred in certain camps.⁸⁶⁻⁸⁹ The value of air sanitation for controlling these epidemics depends upon the extent to which the infections may be air-borne. The conduct of controlled studies using various techniques of disinfecting air and suppressing dust is one of the few means of answering this question.

CONCLUSIONS

The subcommittee offers the following five points to summarize its group judgment concerning the present status of the application of engineering methods to control air-borne infection:

1. The oiling of floors, blankets, and bedding has now developed to the point of practical application in the suppression of dust. Such measures constitute good housekeeping. They reduce bacterial contamination of the air, but there is as yet insufficient evidence that they prevent disease. Dust suppression should be applied wherever practicable in conjunction

with ventilation, ultra-violet irradiation, and disinfectant vapors, when the latter methods are employed.

2. The available evidence strongly indicates that methods of air disinfection (ventilation, ultra-violet irradiation, and glycol vapors) are useful adjuvants to aseptic techniques in the reduction or elimination of air-borne infections in operating rooms and in contagious disease and pediatric wards. Installations are indicated under conditions where there has been demonstrated or there exists potentially a significant incidence of cross-infection or a serious risk to patients. It is essential that competent engineering supervision be available to insure the adequacy of the original installation, to maintain its continued effectiveness, and to protect both personnel and patients.

3. It is not yet possible to compare the relative efficiency of ultra-violet irradiation and glycol vapors. Only the former method has been developed to a point of practical application. Recent designs of glycol vaporizers and automatic control devices give promise that adequately controlled studies may be conducted in the near future. The relative merits of the two procedures will involve such problems as cost, safety, and the consistency of effective operation based upon long experience.

4. The general use of ultra-violet irradiation or disinfectant vapors in schools, barracks, and in specialized industrial environments is not justified at the present time. There is great need for further carefully controlled field studies to define the mechanisms of the spread of infectious disease among these types of populations.

5. There is no justification for the indiscriminate use of ultra-violet light or other methods for disinfecting air in homes, offices, or places of public congregation.

Merit System Administration in Official Health Agencies

JOSEPH W. MOUNTIN, M.D., F.A.P.H.A., BESS A. CHENEY,
AND DONALD F. SIMPSON

*Medical Director, and Personnel Methods Analysts, United States Public Health
Service, Washington, D. C.*

SINCE 1940 a system of personnel administration on a merit basis has been required of state health departments participating in the Public Health Service grant-in-aid programs. There had never been enough qualified health workers, but severe as the personnel shortages were in 1940, they were tremendously intensified during the war years. Physicians, nurses, sanitary engineers, dentists, and laboratory technicians were first to leave public health agencies, many of them to enter the armed forces. Closely following were clerical, administrative and other non-professional employees, who, if not taken into the armed services, were drawn by war jobs and high wages to swollen defense industries. Circumstances were not favorable for the successful operation of a system of personnel administration which admittedly complicated the hiring of workers as compared to direct employment by the state health authority. Yet with heavy odds against success, the merit system with its many advantages to both employer and employee proved itself under the most trying conditions.

The objectives of the merit system have long been recognized as of great significance in public health activities. Public health, perhaps more than any other government service, is dependent on trained and efficient personnel.

Through the merit system, a health department can employ the best qualified and most efficient personnel available, and at the same time offer maximum employment security and opportunity.

In recognition of the trend in state and local governments toward a system of personnel administration based on merit principles, the Social Security Act, which provided for the expansion and improvement of health and welfare services, was amended in August, 1939, to require that state agencies receiving federal grants-in-aid operate under a merit system. A number of states had already adopted civil service laws by the time the merit system requirement was added to those parts of the Social Security Act which were administered by the Children's Bureau and the Social Security Board. The merit system requirement was not included in the part of the Act administered by the Public Health Service. Beginning in January, 1940, however, this requirement was included in the Surgeon General's regulations governing the administration of grants-in-aid.

The Public Health Service Act of 1944 which superseded Title VI of the Social Security Act, included grants for venereal disease control, tuberculosis control, and general health services. Regulations governing administration of grants under the new law required state

health department personnel administration on a merit basis as a condition for participation in these funds. The regulations provided that merit system rules should be submitted to the Public Health Service for review.

At first Public Health Service medical officers who had administrative experience were assigned to review and approve the rules. But both the amount and the technical nature of the work demonstrated the need for a staff trained in personnel methods. Consequently, a special unit was organized in the States Relations Division in July, 1941. The principal duties of the State Personnel Administration Unit, as the new organization came to be known, include reviewing state merit system rules and regulations and classification-compensation plans, advising Public Health Service district personnel on merit system policies and procedures, and consulting with state health departments on merit system administration.

Merit system plans are submitted to Public Health Service district offices for preliminary review. The district administrative analysts examine the organization and technical aspects of the plan. District medical, dental, nursing, and sanitary engineering consultants may also review the general organization of the merit system, but they direct their attention primarily to an analysis of class specifications in their respective fields and the compensation schedules for such classes.

A copy of the merit system plan is forwarded with district comments and recommendations to the State Personnel Administration Unit for review. A detailed analysis is prepared evaluating the plan in relation to the policies of the Public Health Service and accepted personnel standards. Amendments or revisions are suggested to the District Offices for whatever action is necessary to bring the plan into conformity with acceptable standards.

MERIT SYSTEM STANDARDS

The Public Health Service standards are applicable to all state employees rendering services in connection with programs for which the budgets utilize funds administered by the Public Health Service or state funds used for matching, and to persons having administrative responsibility for such programs unless specifically exempted. When the merit system is extended to local health departments, similar standards are applicable to local employees.

MERIT SYSTEM JURISDICTION

A considerable number of the initial rules governing the jurisdiction of the merit system did not meet standards. The exemption of confidential secretaries to state health officers, vital statistics workers, assistant or deputy state health officers, sanitarians, part-time clerks, non-professional laboratory workers, and unskilled laborers was chiefly responsible. One civil service law excluded from the classified service, "all superintendents, directors or other employees in the state government who of necessity must be licensed physicians, surgeons, or dentists."

Such exemptions could be removed by revising the rules in those states which operated under a joint or single agency merit system. The exemptions, while authorized under civil service laws, were not mandatory and health officers filled such positions from registers of eligibles. The solution to this problem set the pattern for meeting many of the conformity issues which arose over statutory provisions.

MERIT SYSTEM ORGANIZATION

Civil service commissions, the oldest form of merit system organization, have been established in 21 jurisdictions. Civil service organization varies from state to state but for the most part all are modeled after the United States Civil Service Commission. The standard

civil service law provides for three commissioners of whom not more than two may be members of the same political party. They are appointed by the state governor to serve for overlapping terms. In most cases the commissioners are reimbursed for incidental costs in connection with official meetings but receive no other compensation. The commission sets the policies, writes the regulations, and supervises the general administration of the merit system program. Specifically, it is responsible for the preparation of classification and compensation plans, a competitive examination system, appeal procedures, and rules and regulations governing the conditions of employment and all personnel actions. To aid in the discharge of these responsibilities, the commission selects a secretary, chief examiner, or personnel director to head a staff of personnel experts and clerical aides.

Joint merit system agencies have been established in 26 jurisdictions. In contrast to the civil service commissions, most of the joint agencies had no statutory support in the beginning, although there has been a trend toward such endorsement during the last two or three years. The joint agencies have usually been established by written agreement of the state agencies participating in grant-in-aid programs. The regulations are generally modeled after the *Draft Rule for a Merit System of Personnel Administration*, published by the Social Security Board in November, 1939.

Merit system councils usually have three members appointed by the participating agencies or by the governor on the recommendation of the agencies. They serve for overlapping terms of office and are paid only expenses incurred in attending official meetings. The qualifications of council members are more strictly defined than are those of civil service commissioners. The members must be "public spirited persons of recognized standing and of

known interest in the improvement of public administration and in the impartial selection of efficient government personnel," according to the Draft Rule. They may not have held political office, nor have been officers in political organizations, nor have been employed by a participating agency during the year preceding appointment.

Civil service commissions are empowered by law to establish and administer merit systems. Most functions of the merit system councils, in contrast, are advisory. The rules and regulations are written and classification and compensation plans prepared by the agencies with technical advice from the councils. Like the civil service commissions, merit system councils hear appeals, or appoint impartial boards to hold hearings for them, select merit system supervisors, and promote public understanding of the merit system.

Four state health departments still operate their own merit systems. The Public Health Service gives only temporary approval to such single agency systems, pending organization of joint agencies or civil service commissions. Written justification is required from the state health officer establishing the necessity for a single agency. Four other state health departments originally established single agency merit systems. Three were superseded by joint agencies and one was placed under the jurisdiction of the state civil service commission.

The merit system supervisor is chiefly responsible for the administration of merit system procedures. The rules usually provide that he shall have training and experience in personnel management and be of known sympathy toward the merit principle in public service. Most merit system supervisors are selected from registers of eligibles established from the results of open competitive examinations. The major functions of the supervisors are: (1) to prepare, administer, and score examinations; (2)

to establish and maintain registers of eligibles; (3) to determine the availability of eligibles for appointment; (4) to certify eligibles for appointment; (5) to determine the adequacy of existing registers and schedule examinations in accordance therewith; and (6) to develop and administer such other procedures as the council or merit system rules may require.

The merit system rules did not conform to the standards used by the Public Health Service in reviewing methods of personnel administration in four civil service, seven joint agency, and four single agency jurisdictions. Under some civil service laws administrative responsibility is divided among the commissioners instead of being delegated to a personnel director. This lack of integration may have contributed to the difficulties of personnel administration experienced under war conditions. In these civil service states there are more health department employees without permanent status than in most merit system jurisdictions. Some civil service commissions have held no formal examinations for four or five years.

Personnel procedures must be flexible enough to meet changing economic, political, and social conditions. Civil service laws which include detailed procedures tend to become obsolete. It is therefore preferable to establish the merit principle in law and the procedures for its application in administrative rules and regulations; otherwise the rigidity imposed may be too restrictive for efficient and impartial administration.

Both joint and single agency merit systems are more flexible because administrative rules are comparatively easy to revise. They have been criticised principally on the high cost of administration per employee, restricted employment opportunities, and wage differentials in comparison with non-participating state agencies.

CLASSIFICATION PLANS

The classification plan including specifications for all classes of positions in the approved health department plan serves two purposes. It is designed "to lay the foundation for equitable treatment for public employees by the accurate definition, orderly arrangement, and fair evaluation of positions in the public service,"¹ and to provide appointing authorities with a systematic method of employing and evaluating personnel. Specifications for classes of positions are as necessary and important to an appointing authority as specifications for building materials are to a contractor. Unless the employing agent knows the exact nature of a job, with the qualifications necessary for competent performance, he will not be able to select the best available worker.

Health department classification plans are submitted to the Public Health Service for review. The titles, definitions, examples of work, and minimum qualifications of specifications included in the plans frequently need revision to bring them into conformity with acceptable standards. The specifications usually describe the technical operations satisfactorily but often do not include the degree of supervision under which the work will be performed, the responsibility for the work of others, and properly defined minimum qualifications.

Professional titles should be applied only to professional classes. For example, the title "bacteriologist" has been used for a laboratory position which did not require professional training. The Public Health Service recommends the use of a title such as "laboratory technician." Occasionally titles were applied which were unrelated to the duties described. In one state the truck driver and photographic equipment operator for the Bureau of Health Education was called "Assistant—Bureau of Health Education."

Class definitions should be short, gen-

eral statements of the principal duties and responsibilities of the class which distinguish it from other classes. They should be clear enough so that an accurate organization chart could be drawn without additional information. This technique is used by the State Personnel Administration Unit analysts in reviewing classification plans.

Concise statements which illustrate the duties and responsibilities typical of the class should be included in the examples of work. It is occasionally apparent from the class definition that certain important and typical examples have been omitted. The specification for an assistant director of a major division, for example, should include the duty of acting for the division director in his absence. The examples of work should indicate those performed under supervision and those on the initiative of the employee. Essentially incidental duties should not be included. Specifications should not be "written up" to make a job appear more difficult or more responsible than it actually is.

Minimum qualifications necessary for satisfactory job performance should specify the amount, recency, and kinds of both education and experience which the applicant must have. They should be appropriate to the duties, responsibilities, and examples of work in the specifications, for only then will the specifications provide an adequate basis for evaluating applications or for preparing examinations.

The amount of formal education required sometimes is unrelated to the duties and responsibilities of the class. Specifications for vital statistics, laboratory, and health education directors which required M.D. degrees have been submitted in which the duties and responsibilities failed to establish any necessity for a medical education. The substitution of experience for training sometimes serves to nullify educational standards. Specifications have been

submitted for certain positions which required college graduation and yet permitted year for year substitution of experience for training up to a maximum of eight years.

COMPENSATION PLANS

A compensation plan must include all positions in the classification plan. Salary schedules for each class are reviewed in terms of: (1) the application of the principle of equal pay for equal work, (2) the adjustment of the salary range to the responsibility and difficulty of the work involved, (3) a realistic recognition of prevailing wage levels for similar positions in private industry and other public agencies in the locality, and (4) the economic law of supply and demand in relation to current labor markets. Each salary schedule should include maximum, minimum, and, unless prohibited by law, intervening rates of pay.

Almost all the rules establishing compensation plans were well written except those dealing with special wartime provisions. In March, 1943, most of the states relaxed standards to allow original appointments at a pay level higher than the minimum rate. The Public Health Service agreed to this procedure but required safeguards which provided: (1) appointments should be made above the minimum only for the duration of the war emergency; (2) such appointments should be made only at one of the regularly established intervening pay steps; (3) all eligibles higher on a register should be offered the job at the higher entrance rate; (4) no employees in the class should be below the higher rate when an appointment above the minimum is made, and (5) all appointments above the minimum should be approved by the merit system council or civil service commission following written request for such approval by the appointing authority.

The use of formal compensation plans

as instruments of personnel management was unfamiliar to many of the state health agencies which had no previous experience with a merit system of personnel administration. An analysis of the salary schedules for a typical health department showed that there were 85 classes with 48 different salary ranges: 32 applying to but one class, 7 applying to two, and 9 applying to more than two. In contrast there are fewer than fifty different salary ranges for the thousands of federal civil service classes. Comparatively few salary ranges are needed when compensation is determined on the basis of duties and responsibilities and in accordance with the principle of equal pay for equal work.

According to generally accepted standards, the salary range from minimum to maximum should be between 20 and 25 per cent of the minimum pay rate. In the compensation plan studied 29 ranges were more than 25 per cent, 13 less than 20 per cent, and only 6 fell within the generally accepted range.

A number of the salary scales with identical minimum pay rates extended to different maximum rates. For example, there were five salary scales starting at \$175 which extended to maximum rates of \$200, \$215, \$230, \$235, and \$250. When duties and responsibilities of classes are similar enough to justify identical entrance salaries, the only reason for varying maximum rates is to provide for long and efficient service in those classes which offer no promotional opportunities.

RECRUITMENT

The recruitment of qualified workers is an important function of the personnel agency. Most merit system organizations in the past have taken advantage of a favorable employers' market instead of conducting positive and aggressive recruiting. By January, 1942, the shortage of qualified personnel had reached a critical stage. Health

departments sought to overcome the shortages by lowering employment standards. As an alternative certain changes in methods of recruitment and employment were suggested. Health departments were urged (1) to eliminate state and local residence requirements and discrimination on the basis of sex or marital status, (2) to increase salaries, (3) to provide for continuous receipt of applications and administration of examinations whenever enough applicants to assure adequate competition were available, (4) to administer joint examinations for two or more jurisdictions with common classes of positions, (5) to remove the 6 months' limitation on provisional appointments, and (6) to provide certification of more than the required number of names for each vacancy from those registers where availability of applicants changed rapidly.

At the same time it was suggested that if these recommendations did not solve recruiting problems, the states might establish war emergency classes involving a lesser degree of responsibility, closer supervision, and qualifications modified as to education and experience. Positions in war emergency classes should be filled from registers established according to the results of relatively simple examinations of general intelligence and aptitude for a particular job. Titles such as Acting Health Officer, Public Health Nursing Aide, or Engineering Assistant were suggested to distinguish them from regularly constituted classes meeting appropriate standards on minimum qualifications.

EXAMINATIONS

The process of selection by means of competitive tests is indispensable to a merit system of personnel administration. Objective written examinations are by far the most valid, practical, and inexpensive that can be used in the selection of qualified personnel. The

more usual practice among the states has been to give examinations consisting of subjective, essay-type written tests, a rating of training and experience, and an oral interview. Such examinations have been criticised because they fail actually to measure knowledge and ability, do not assure competition, and do not provide absolute impartiality in selection.

The American Public Health Association through its Merit System Unit has been engaged in a program to develop valid and reliable examinations for professional and technical health department positions since May, 1940. Recognizing the acute need for such examinations, both the Public Health Service and the Children's Bureau have given financial support to the program from its inception.

The Merit System Unit prepares examinations in eight major public health fields and nine specialties within those fields. The general categories include public health nursing, public health administration (health officers), public health laboratories, environmental sanitation, sanitary engineering, medical social work, vital statistics, and health education. The specialties within the general categories cover orthopedic nursing, nurse midwifery, industrial nursing, physiotherapy, x-ray technology, pathology, food and drug chemistry, entomology, and nutrition.

The examinations are prepared to fit the needs of the state and local health departments using them. Class specifications setting forth the duties and responsibilities as well as the minimum qualifications pertaining to a group of positions are submitted by the health departments requesting the preparation of examinations. These examinations are outlined according to the subject matter areas which must be covered to measure the knowledge and ability necessary for satisfactory job performance. An examination for the position of labo-

ratory director, for example, may cover such areas as food and drug chemistry, bacteriology, public health laws and regulations, laboratory administration, etc., depending on the kinds of knowledge required in the specifications.

The questions are prepared by persons professionally or technically trained in public health and actually employed in health department positions. They are trained and supervised by subject matter consultants, who are highly qualified by both training and experience, and who have been selected for each field of public health in which examinations are prepared. The consultants also work in close liaison with the psychometrician of the Merit System Unit in editing, classifying, and determining the relative difficulty of every question. The questions are subsequently submitted to a board of expert reviewers for final check. The reviewers rule on the effectiveness of each question as a measuring device and on the level of difficulty assigned each item. On the basis of the comments and recommendations made by the reviewers, the questions are revised and a final draft is prepared by the consultant and the psychometrician. Consultants construct the basic outline of each examination and prepare the preliminary draft. The psychometrician is primarily responsible for the validity and reliability of the examinations. Since evaluation of test results is a necessary part of test construction, the agencies to which tests are supplied are urged to return original or duplicate answer sheets after the tests have been scored and candidates graded.

The American Public Health Association examinations have been very favorably received in all jurisdictions in which they have been used. Many of the states which originally ordered only public health nursing examinations have later asked for tests in the fields of sani-

tary engineering, public health laboratories, environmental sanitation, etc. The work has progressed so far that as of September 1, 1946, 195 A.P.H.A. examinations have been prepared for twenty-five state and three city health departments.

The Merit System Unit has recently expanded its program to include field consultation service. This service will be available to any state or local personnel agency or health department which requests it. The field consultant will be in a position to advise with such agencies, not only on problems directly related to examinations, but also on the other phases of public health personnel procedures.

ELIGIBLE LISTS

After examinations are graded a register of candidates eligible for appointment, arranged according to grade, is established for each class. The procedures followed in establishing and using registers were generally acceptable. Sometimes the method of removing the names of eligibles was too arbitrary. Names should be removed only when eligibles cannot be located, when any state job has been declined, or when three appointments have been refused.

In order to provide for reemployment of persons who resign or who are separated without prejudice, reemployment registers should be established or the rules should contain a formula for inserting the names of permanent employees on the original registers in approximately the same order as originally placed. A few of the states did not include such a formula nor satisfactory procedures for the removal of names from registers.

CERTIFICATION

Upon requisition from an appointing authority, the merit system supervisor certifies the highest ranking available

persons on the register. Appointing authorities sometimes were allowed to requisition personnel according to special requirements not listed in the specifications. Unless selective certification is properly safeguarded it may favor applicants of lesser ability at the expense of the better qualified personnel higher on the register. Selective certification is a practical means for filling a position which requires both generalized knowledge and specialized qualifications included usually as an option in the class specification. For example, a health department may need a county public health nurse who can devote two-thirds of her time to general public health nursing and the remaining third to industrial nursing. By including in the requisition special and additional qualifications in the field of industrial nursing, it is neither necessary to establish a separate class for this position nor to hold a special examination for it.

The rules should specify the number to be certified for each vacancy in a class. To provide no restriction on the choice of an appointing authority would completely destroy the merit principle in the selection of personnel. The common practice has been to certify three names. During the war years many states permitted certification of the whole register of available eligibles in the interests of speeding up appointments.

APPOINTMENTS

Although state rules governing permanent appointment were generally satisfactory, those for probationary, provisional, temporary, emergency, and war emergency appointments were in some cases not in conformity with acceptable standards. Probationary periods of established duration were not always provided for in the rules. A statement that the probationary period had been satisfactorily completed was not always required prior to per-

manent appointment. Since the probation period is an essential part of the examination process, no employee should gain permanent status through default. Provisions for salary advancements, promotions, or transfers during the probation period were sometimes not in accordance with accepted standards.

Provisional, temporary, emergency, and war emergency appointments often were not clearly defined in the rules. Provisional appointments should be limited to a period of 6 months, or at most until registers of eligibles are established, whichever is sooner. (The Public Health Service waived this requirement for the duration of the war.) Emergency appointments should be made only when there is an immediate and urgent need for persons who cannot be obtained from appropriate registers. Further, they should be limited to a period no longer than 30 days and repeated appointments should not be made since emergency employees can be replaced with regular appointees if the emergency lasts more than 30 days. Temporary appointments should be made for short term jobs from registers of eligibles willing to accept them. War emergency appointments are no longer necessary.

SUPPLEMENTARY RULES AND REGULATIONS

In order to protect the merit principle, public employees are prohibited in most merit system rules from taking an active role in party management, election campaigns, and soliciting or contributing campaign funds. However, each employee retains the right to vote as he pleases and to express privately his opinions on all public issues.

A system of personnel administration should include regulations governing vacation, sick, military, educational, and other types of leave; periodic service ratings; and maintenance of adequate personnel records. Such regulations may

not be included in the merit system rule. In many jurisdictions these activities are regulated by standard practices which are not in written form.

The rules on payroll certification generally conformed to accepted standards. However, several states provided for payroll audits as infrequently as once every 3 or 6 months, or as ambiguously as "from time to time." The merit system supervisor should certify that each person on the pay roll is legally employed and that the amounts paid are in accordance with the compensation plan. Pre-audits of all health department pay rolls at every pay period are preferred but post-audits are accepted if made within 2 weeks following payment.

The right of appeal from administrative decisions concerning examinations, classifications, and disciplinary actions is recognized in all the civil service or merit system rules. The rules provide that the civil service commission or merit system council shall hear such appeals or shall appoint an impartial board to hold hearings on its behalf. A definite time limit for filing appeals should be established to avoid so delaying proceedings as to work a hardship on the plaintiff and to result in loss of evidence or testimony. The conditions under which appeals can be brought should also be defined or limited, in order that the merit system council or civil service commission may not be overburdened.

Many state health departments need to develop regulations governing such internal procedures as appointments, transfers, separations, salary advancements and promotions, attendance and leave, individual employee records, and systems of periodic service ratings. In addition most of them must soon terminate such wartime procedures as the use of war emergency classes and war duration appointments. This will involve either the preparation of new

class specifications or the revision of existing specifications. Readjustments in salary schedules will have to be made and examination techniques revised. Perhaps the most difficult problems will be the replacement of war service appointees and the application of new laws and regulations concerning veteran preference.

CONCLUSION

During the war personnel shortages were so severe that regular merit system employment procedures were frequently suspended. Competitive examinations for health department positions could not be held because of an insufficient number of candidates. Nevertheless, records of 43 health departments, em-

ploying 21,451 workers, show that about half, or 10,992, have merit status; 8,795 hold provisional, emergency, or war emergency appointments established by merit system rules, and only 1,664 were in exempt classes. These figures are derived from reports on the status of personnel in state and territorial health departments on July 1, 1945. Detailed figures are shown in the accompanying table.

The number of health department employees with merit status is evidence that, in spite of wartime difficulties, great progress has been made in placing personnel administration on a merit basis. During the war the Public Health Service was unable to provide state

health agencies with the services they requested. The State Personnel Administration Unit could seldom assist, for example, in preparing class specifications, developing compensation plans, establishing personnel record systems, rating scales, and other instruments of personnel management. The Public Health Service now plans not only to provide the assistance requested by health departments, but also, through periodic reviews of personnel activities, to determine how best to serve in strengthening their merit systems.

Proposed Report on the Educational Qualifications of Public Health Engineers^{*†}

THE term "public health engineer" as used in this report refers to the sanitary engineer, employed by a public health agency, who is trained in methods for the control and proper use of factors of the environment to the end that the public health is improved or protected.

The term "public health engineering" as used in this report includes the public health aspects of all types of environmental conditions whose control is based upon engineering principles. All procedures of public health agencies that depend upon engineering materials or methods for environmental conditions should be considered as public health engineering activities.

I. GENERAL SCOPE OF ENGINEERS IN PUBLIC HEALTH PROGRAMS

Sanitary engineers with basic training in civil engineering early developed competence in water supply, sewage, and waste disposal. In order adequately to meet the problems of design and operation of such sanitary work, a knowledge of the chemistry and biology of these services became essential. This

enlarged their sphere of interest, and in the course of time caused them to take an active part in all those problems concerned with the promotion and preservation of the public health to which engineers are able to contribute a significant solution.

The practice of public health engineering includes not only the activities of engineers in official health agencies in their investigations, review of plans, and supervision of the operation of sanitary works, but also the functions of engineers in private practice or in government organizations other than health agencies in the design, operation, and control of sanitary works. In order to be qualified to review plans and supervise operations, therefore, the public health engineer must be trained and qualified not only to advise on problems of sanitation, but also to design and construct sanitary works.

Public health activities may be divided into two distinct but closely interrelated fields, one having to do with the human element and the other with the environment. The first is normally the field of the physician and the nurse, while the second is that of the engineer and other sanitation personnel. There is no distinct separation between these activities, but there is a middle ground in which the activities of the physician and engineer merge. Therefore, successful operation of a public health program demands administrative participation and careful planning by both physician and engineer.

A complete public health program must include adequate provision for

^{*} This report was presented by the Committee on Professional Education to the Governing Council on November 13, 1946, and was approved in principle by the Governing Council with the recommendation that the report be published in the *January Journal* and, if no serious criticisms are received from members and Fellows of the Association, the report becomes final and, adopted as an official report of the Association as of March 1, 1947.

This report, like all other statements of the committee on professional and technical qualifications in public health, is subject to periodic revision in order that it may be kept abreast of the best thought.

[†] This proposed report is a revision of the report on the Educational Qualifications of Public Health Engineers approved by the Governing Council on October 5, 1937.

both the human element and the environment. The health officer aided by an adequate and competent engineering staff can assure the needed administrative assistance and technical advice necessary to provide a complete program. Not only is the public health engineer responsible for the engineering aspects of strictly public health phases of community life but he must also participate and assist in planning, designing, building, and operating of other engineering facilities, which are the primary responsibility of other branches of government, in order to promote and protect public health.

It is evident then that the department of health, through its engineering division or bureau, does not operate as an isolated unit, but that it contributes to the maintenance of an orderly and properly functioning society in coöperation with many other departments of government having engineering functions. A broad concept of the social, political, and economic forces that operate in the community is essential to the recognition and development of such a program.

There is a considerable expansion of health programs taking place both at state and local levels as well as in industry. The number of engineers in public health work must be increased enormously if the needs are to be met. Expansion of related programs of public works construction, slum clearance, and urban redevelopment, industrial activity and stream pollution control will require additional numbers of similarly trained men. Conservative estimates place the number of public health engineers needed, in addition to those on the job now, at more than 1,000 to meet only the minimum needs for local health services. It is recommended that a population unit of 50,000 or more requires the services of at least one public health engineer plus an adequate number of assistants. Only by the

establishment of high professional standards, with a corresponding increase in salaries, can the required number of competent persons be obtained and their services retained.

II. THE ACTIVITIES AND FUNCTIONS OF ENGINEERS IN PUBLIC HEALTH

One of the major activities of public health engineers is that of supervising the development and operation of sanitary works in order to control properly those aspects that may affect the public health. The engineering procedures involved and the place of the public health engineer in the supervision, development and operation of such works are:

- a. Investigating and planning
- b. Designing and preparing specifications
- c. Construction
- d. Maintenance and operation

Except as discussed later, the design and construction of sanitary works is commonly assigned to engineers in private or consulting practice, public engineering organizations developed for this specific purpose, such as the New York Board of Water Supply or the Chicago Sanitary District, and the personnel of existing governmental agencies, such as the Department of Public Works. The maintenance and operation of the structures is then generally taken over by existing or specially organized departments or appropriate political subdivisions.

The proper development and operation of sanitary works are matters of public concern in general and of public health in particular. Since profit or other economic motives are often associated with the development and operation of sanitary works, and since there may be a conflict of interest between different regions, communities, or industries and their sanitary needs, supervision and regulation is placed in governmental agencies including the

engineering subdivision of health departments. Briefly, those organizations are entrusted with the following activities:

- e. Investigation of sanitary needs, and stimulation to provide necessary remedial measures
- f. Advice relative to and approval of proposed works and approval of completed works
- g. Supervision of operation and maintenance of existing works
- h. Development and enforcement of rules and regulations

Procedures (e) to (h) are complementary to the fundamental engineering procedures involved in the development and operation of sanitary works procedures (a) to (d) and have been interpolated for the purpose of establishing a reasonable system of checks and balances in the interest of health and welfare. Competently to fulfil procedures (e) to (h) the responsible engineer must possess the fundamental qualifications required by procedures (a) to (d) as well as additional qualifications related to the public health and welfare aspects of these activities. In the federal government and in some states and their subdivisions, the design, construction, and operation of sanitary works connected with governmental institutions and the design, construction, and operation of mosquito-control and rodent-control projects are assigned to the engineering organizations of their respective health agencies.

Public health engineering includes not only supervision of the development and operation of sanitary works as outlined above, but also participation in the planning, design, construction, operation, and maintenance of other physical elements that contribute to the support of community life so that the protection and promotion of public health can be assured. Some of these other physical elements are: dwellings; structures, and equipment used to produce, process, and distribute the food supply; environmental conditions which support disease-bearing insects and rodent life, and the

growth of noxious weeds; industrial structures and equipment with especial reference to the effect on the air breathed in such industries as well as the other physical hazards therein.

The following are listed as public health engineering activities, as now carried on:

1. Water supply and treatment; design and installation of sewers, sewage and industrial waste disposal; stream pollution control; bathing place control; and mosquito control measures.
2. Municipal and rural waste disposal and insect, rodent, vermin and weed control.
3. Food sanitation, including the production and pasteurization of milk and the manufacture of ice cream and other dairy products; the sanitary production of shellfish, and the production, storage, and distribution of meat, poultry, pastry, bakery goods, fish, and other foods as well as the sanitation of eating and drinking establishments.
4. The sanitation of schools, camps, public places, swimming pools, and recreational areas.
5. Programs to promote healthful housing for all people.
6. Industrial hygiene and sanitation. This involves those special engineering problems incident to industrial processes and includes the many features of environmental sanitation. Industrial sanitation should, therefore, be under the direction of a public health engineer.
7. In cities particularly, proper city planning, heating, lighting, and ventilation of buildings, plumbing, aerial pollution, and noise. These problems are largely engineering in character. Any program to influence them for the benefit of public health must be based on engineering investigations and solutions.

III. THE EDUCATIONAL BACKGROUND OF PUBLIC HEALTH ENGINEERS

Public health engineers must possess two distinct and essential educational qualifications: (a) basic education and training in engineering, and (b) specialized knowledge and ability in sanitary science, sanitary engineering, and public health.

a. *Basic Engineering Education*

The public health engineer should be a graduate of a full four year or longer course

leading to a bachelor's or higher degree* at a college or university of recognized standing† with the major study and the basis of the degree in a course such as sanitary or public health engineering, or the sanitary option in civil engineering. In the case of public health engineers entering industrial sanitation, mechanical or chemical engineering is preferred.

In so far as the academic requirements are concerned, the basic education of the engineer should make him eligible for admission to examination for licensure to practise professional engineering in the state of his employment.

b. Specialized Education and Training

The varied functions of a public health engineer necessitate additional education beyond that ordinarily acquired by basic training in engineering. Successful performance in his field requires: (a) an intimate and working knowledge of the physical, chemical, biological, and engineering sciences upon which the sanitary control of the environment is based, and (b) the ability to identify, evaluate, and explain in terms of their public health implications those environmental factors that will promote and protect health or those that are capable of injuring health.

This specialized knowledge lies mainly in three fields: (1) sanitary science, (2) sanitary engineering, and (3) public health. The elements of these are indicated in the outline of graduate education, Section IV. In the rigorous undergraduate engineering curriculum the amount of time that can be allotted to specialized study in these three fields without impairing the basic engineering education is quite limited—generally not more than about 15 per cent of the total scheduled instruction. Adequate preparation of an engineer for a career in public health requires one or more years of specialized study as outlined in Sec-

tion IV and a period of supervised experience in addition to the minimum of four years required for graduation in engineering. However, to enable the graduate in engineering to begin work and gain experience and to prepare him for graduate study it is desirable that his undergraduate program should include as much instruction as possible in the fundamental sanitary sciences—especially bacteriology and chemistry—and in the principles of sanitary engineering and public health.

The program of study, preparing for a career in public health engineering, falls into three categories:

1. Sanitary Options in Four-year Undergraduate Curricula of Civil Engineering—In 1944 twenty-three such curricula remained accredited by the Engineers' Council for Professional Development.* The accredited options, for which information is available, allotted from 8 to 20 per cent of the period of study to the subjects of primary importance to sanitary engineers; namely, chemistry (beyond freshman chemistry), biology (including bacteriology), hydrology or hydraulic engineering, sanitary engineering, and public health. There are no sanitary options in chemical and mechanical engineering, those most closely allied to industrial hygiene.

2. Four year Undergraduate Curricula in Sanitary Engineering—In 1944 three such curricula remained accredited by the Engineers' Council for Professional Development. One of these three accredited curricula had been discontinued by its institution. Registration for programs of this type has long been very low and the outlook for a continuation of these programs is uncertain. The accredited curricula allotted from 13 to 25 per cent of the period of study to the subjects of primary importance to sanitary engineers (see "1" above). None of these curricula is oriented particularly toward the practice of industrial hygiene.

3. Graduate Curricula in Sanitary Engineering and Public Health—These include two general types of programs, those in which the major study and graduate degree are in sanitary engineering and those in which the major study and degree are in public health. Such programs provide opportunities for engineers with little or no training in public health engineering to develop a sufficient background to

* In making this recommendation the American Public Health Association expressly recognizes that there are many persons now actively engaged in public health work who are lacking in formal education but whose training or experience should be accepted as fully equivalent to the basic engineering education defined above. The basis of substitution shall be at least two years of appropriate training or experience equivalent to one year of formal engineering education. Such persons who have sufficient equivalent training or experience to substitute for the accredited engineering education they lack shall be considered professional engineers for the purpose of this report.

† A college or university of recognized standing is defined as one which is accredited by a national or regional accrediting association such as the Association of American Universities, or the New England, Middle State, North Central, Southern, or Northwest Association of Secondary or Higher Schools, or one whose engineering curricula have been accredited by the Engineers' Council for Professional Development.

* At the present time the Engineers' Council for Professional Development is the only accrediting agency of national scope which examines and accredits curricula in sanitary engineering and sanitary option of civil engineering.

begin work in public health. They also provide advanced graduate instruction for those who have completed undergraduate programs in sanitary options or sanitary engineering. Either of the two types of programs should be accepted as satisfactory for these purposes if they include adequate instruction in each of the three essential fields of knowledge previously outlined and enough choice of electives to meet the needs of students with varying backgrounds of previous training and experience. As yet there are no accrediting agencies that examine and accredit graduate curricula in sanitary or public health engineering.

As a minimum for initial employment as a public health engineer the graduate engineer should have completed an approved undergraduate sanitary option or sanitary engineering program; or, in addition to graduation in engineering, should have received an equivalent amount and similar character of approved postgraduate education or in-service training. Such postgraduate training can best be obtained through study in an approved educational institution but may be provided by postgraduate self-education or in-service training during a period of probationary employment under competent public health engineering supervision. A young engineer, at first occupied in a subordinate position, should work under close public health engineering supervision until he has prepared himself by experience or graduate study for positions of major responsibility. Graduate education affords the greatest assurance that the public health engineer will become both broadly competent and well grounded in the subjects that are fundamental to sanitary progress.

IV. GRADUATE EDUCATION

The true value of the public health engineer rests squarely on his ability within his professional field.

Because of the wide difference in the technical knowledge required in the various fields of public health engineering activity, opportunity should be afforded for some specialization. Depending upon the student's preparation, a suitable program of graduate study should be developed from the following elements of sanitary science, engineering technology, and public health practice.

a. Sanitary sciences including (but not limited to): bacteriology, chemistry, parasitology, planktology, entomology and human

physiology as related to problems of public health engineering interest.

b. The principles and practices of engineering analysis, design and operation as applied to works and projects for the protection and promotion of the public health including (but not limited to) the following: water supply and purification, sewerage and sewage treatment, the collection and disposal of municipal, rural and industrial wastes; projects for the control of insect, rodent, and other vectors of disease transmission; the engineering and administrative phases of food and milk sanitation; the sanitation of buildings including ventilation, air conditioning, heating, plumbing, and illumination; housing; industrial sanitation with particular reference to those industrial health hazards the correction of which is largely an engineering problem.

c. The principles of public health including (but not limited to) the following: public health administration sufficient to give the student a clear understanding of the purposes, functions, and legal bases of the general public health program and the responsibilities of the engineer within that program; epidemiology and communicable disease control; statistical methods in sanitary engineering and public health practice.

Emphasis should be placed upon the fundamental scientific engineering and public health content of the subject matter presented—the student being supervised and guided in his development of possible techniques and practices based upon sound fundamental concepts.

The type of institution best fitted to give the instruction is a university which includes both a faculty of engineering and a faculty of public health, and in which close coöperation is maintained between the members of the two faculties who are responsible for instruction in public health engineering.

V. CLASSIFICATION OF PUBLIC HEALTH ENGINEERS

In any organization having a staff of engineers, classification is necessary. In general such classification automatically occurs and it is a general requirement under usual civil service procedures. However, lack of uni-

formity in classification exists among the various health agencies employing engineers. The following classification with educational and experience requirements is suggested. It is based on the requirements of several states, federal Civil Service, the United States Public Health Service for Commissioned Officers, and the classification of engineers as adopted by the American Society of Civil Engineers.

The education, training, and experience stated in the classification should be regarded as the minimum that is normally acceptable. It is not intended that the qualifications should be retroactive but rather that they should apply to the selection of new employees and serve as a guide in the future advancement of sanitary engineering personnel.

Because of the present limited supply of qualified public health engineers, it is proposed that in any grade, three years of acceptable experience in public health engineering under competent supervision may be substituted for the one year of graduate study set forth in this report. However, the advantages of specialized graduate study in the sound and early development of public health engineers for positions of responsibility are recognized. Therefore, as soon as practicable, at least one academic year of approved graduate study as described in Section IV should be made a basic requirement for appointment or promotion to Grade III or to higher grades in this classification.

Education and Experience

The minimum educational requirements for all grades are: (1) graduation in engineering from a college or university of recognized standing; (2) satisfaction of academic requirements for admission to examination for licensure to practise engineering in the particular state; and (3) completion of an approved undergraduate sanitary option or sanitary engineering program

or, lacking such training, an equivalent amount of postgraduate orientation. Such postgraduate training may consist of at least three months of approved university guidance; or a like period of well rounded and systematic in-service orientation and supervised practice. Tentative or provisional appointments may be authorized for graduate engineers without public health engineering training or experience to allow a sufficient period for graduate study or in-service training to qualify them for permanent classification.

With the exception of Grades I and II, specialized education should include, in addition to the minimum educational requirements, at least one academic year of graduate study in a recognized institution of learning leading to a graduate degree and with major study in sanitary science, sanitary engineering, and public health. In lieu of a year of graduate study, three years of suitable practice under the supervision of a competent public health engineer in public health work may be substituted *provided* that, (1) such substitutions of experience for graduate study normally should not be allowed for grades higher than Grade III, and (2) a sanitary engineer who later completes a year or more of graduate study should receive equivalent credit in his classification for the years of experience previously substituted in lieu of graduate study.

Attainment of the doctor's degree in sanitary engineering or in public health if based on special studies in the field of public health engineering in a school of recognized standing should be considered as the equivalent of and may be substituted for a part of the experience requirements of the classification below as follows: Grade III—one year; Grade IV—two years; and Grade V—three years.

Classification

The qualifications for each grade

should conform with the educational requirements or equivalent experience as described above in addition to the experience indicated below:

Grade I—No experience required.

Grade II—At least one year of suitable experience in sanitary engineering work under competent supervision.

Grade III—At least two years of suitable experience in sanitary engineering work in a grade comparable to Grade II, of which at least one year of the total experience must be in public health work. (Total 3 years sanitary engineering, 1 of them in a public health agency.)

Grade IV—At least two years of sanitary engineering experience in a grade comparable to Grade III, of which at least two years of the total experience must be in a responsible position in public health work. (Total 5 years sanitary engineering, 3 of them in public health agency.)

Grade V—At least five years of engineering experience in a grade comparable to Grade IV, of which at least five years of the total experience must be in a responsible position in public health work. (Total 10 years sanitary engineering, 5 of them in public health agency.)

Personal Qualities

To attain success in full measure, public health engineers should not only be competent in their field of learning and practice but should also be able to establish and maintain favorable relations in their own department and with the public on the basis of creative ability, far-sighted leadership, sound

engineering judgment, common sense, honesty, and industry.

VI. QUALIFICATIONS FOR DIRECTING PERSONNEL

Director

The qualifications for the position of Director of a Division of Sanitation (however designated) in a health department will vary depending upon the size of the division and the responsibilities of the position. He should have the educational requirements set forth for all public health engineers, a general knowledge of all phases of public health engineering, and an intimate knowledge of those problems which are of importance in the particular area or community in which he is to be employed. He should have the ability to organize and direct the work of his division.

In small health units where only one employee is engaged in environmental sanitation activities, this employee should meet the qualifications of one of the public health engineering grades unless he is working under the technical direction of a public health engineer of the staff of an overlying governmental health agency.

Assistant Director

An Assistant Director should have the qualifications for the next grade below that in which the director is classified.

Achievements of UNRRA as an International Health Organization

WILBUR A. SAWYER, M.D., LL.D., F.A.P.H.A.

*Director of Health, United Nations Relief and Rehabilitation Administration,
Washington, D. C.*

SO astounding is the magnitude of the overall performance of the United Nations Relief and Rehabilitation Administration, with its mammoth shipments to war-ravaged countries of food, clothing, agricultural seeds, implements, and other essential supplies, that the strictly health functions are dwarfed by comparison. Nevertheless, in order to meet its responsibilities during the emergency, the Health Division of UNRRA had to expand until it became by far the largest international health organization which the world has yet seen. This is true even if the cooperating Division of Medical and Sanitation Supplies* is not included.

The extent of UNRRA's operations was dramatically illustrated by a comment of Mr. Noel-Baker¹ at the recent session of the Council of UNRRA at Geneva:

During the war I was a Minister under Mr. Churchill in our Department of War Transport, and month by month I used to watch the convoys which brought to Britain the food and the raw materials with which we fought the war. The scale of UNRRA's supply operations each month is now equal to the total import programme of the United Kingdom in those historic times.

For UNRRA's entire period of active operations lasting about three years, the

total budget amounts to approximately 3 billion 7 hundred million dollars. When the Administration closes its books next year it is estimated that its health work will account for close to 168 million dollars. The largest portion of this amount, or about 146 million dollars, will have been spent for procurement and shipment of medical and sanitation supplies. By June 30, 1946, 105,000 tons of sera and vaccines, chemicals and drugs, hospital equipment, and laboratory supplies had already been dispatched, and about an equal amount was still to go forward. The estimate of 22 million dollars for the health activities exclusive of expenditures for supplies was reached by prorating the total estimated operational and administrative expenditures up to December 31, 1946, according to the numbers of international employees engaged in health and the number in the total functions and thus determining the share belonging to health.

The maximum annual expenditure of UNRRA for health is that for 1946, estimated as about 14 million dollars for the activities of the Health Division plus 68 million dollars for the procurement and shipment of medical and sanitation supplies. This gives an estimated sum of 82 million dollars for health, medicine, and sanitation during that year. The annual sum for health activities was substantially increased by allotments by certain governments from the proceeds of sales of part of their

* The Division of Medical and Sanitation Supplies, responsible for procurement and distribution, is in the Bureau of Supply, while the Health Division, under the Director of Health, is in the Bureau of Services.

UNRRA supplies. Such sales to persons who could afford to buy were permitted on condition that the net proceeds in local currency should be turned back into relief and rehabilitation activities.

The size of UNRRA's effort in the field of international health can best be appreciated if we mention for comparison a few other important annual health budgets. The League of Nations Health Organization had the equivalent of U. S. \$414,078 in its largest annual budget, the one for 1931, and did valuable pioneering work with these resources. The Interim Commission of the World Health Organization is reported to have a budget of \$300,000 for the remainder of 1946 and \$1,000,000 for 1947. The International Health Division of the Rocke-

feller Foundation for the calendar year 1945 had a budget of \$2,200,000 for its regular program and expended also \$157,016 from the special war funds of the Rockefeller Foundation Health Commission. The United States Public Health Service has a total budget for the fiscal year ending June 30, 1947, of \$88,423,516, including \$290,700 for its new Office of International Health Relations. All the 48 states of the United States of America together appropriated about 50 million dollars for health for the year ending June 30, 1946, and the corresponding figure for the local governments is about 70 million. These comparisons bring out the magnitude of UNRRA's total expenditures for health. They had to be large because the requirements for relief health services and

supplies were extreme at this time of unprecedented emergency.

THE STAFF OF THE HEALTH DIVISION

The professional staff of the Health Division at Headquarters in Washington; at the European Regional Office in London, in the China Office, in the displaced persons operations in Germany, and in the Missions to the several assisted countries, is shown by numbers, professions, and nationality in Tables 1 and 2, as of June 30, 1946. At that time recruitment of new personnel ceased and numbers were already beginning to decrease.

The recruitment of a large professional staff during the war was extremely

difficult. In Great Britain and the United States, military needs had priority. Many other areas which were drawn on later were at first inaccessible. The Surgeon General of the United States Public Health Service and the Chief Medical Officer of the British Ministry of Health appreciated the international importance of the health activities of UNRRA and helped arrange for the temporary release of experienced personnel from positions in their countries. The U. S. Public Health Service also assigned many of its commissioned officers to service with UNRRA and in September, 1946, there still remained on duty with the Health Division 34 medical and 4 dental of-

ficers, 66 nurses, and 16 sanitary engineers.

The international professional staff was recruited principally from the 48 nations now participating in UNRRA and on as broad an international basis as possible. From Table 2 it will be seen that the 1,134 professional persons in the international ("Class I") category, included nationals of 35 countries and a few classified as stateless or unknown. The posts of greater responsibility were also widely distributed among the nations, as will be illustrated by a few examples. At Headquarters in Washington, the Director of Health came from the United States, the Deputy Director of Health from Czechoslovakia, the Chief of the Far Eastern Branch from China, the Chief of the Epidemic Control Branch from Brazil, and the Chief of the Branch of Medical and Sanitation Supplies from the United Kingdom. In the European Regional Office, the Regional Director of Health is from the United Kingdom, his Deputy from the United States, and the Chief of the Branch on Medical Services to Displaced Persons from France.

Chief Medical Officers for Country Missions and the China Office have been drawn from many countries; to cite only a few examples, from Yugoslavia for China, from Greece for Ethiopia, from the United States for Poland, and from the United Kingdom for Italy and Greece. The Chief Field Medical Officer in China is from El Salvador.

The international doctors and nurses fall into two categories, those with public health training and experience and those primarily concerned with the care of the sick. The public health group was invaluable in the administrative and supervisory offices, and in field work in their specialties. Most of the clinical staff were assigned to assembly centers for displaced persons or to hospitals and clinics for the general population, although a few were primarily

engaged in teaching and demonstration. The volume of accomplishment was far beyond what the size of the UNRRA staff would indicate, for staff members worked side by side with a much larger personnel of the local health departments and medical institutions. In China, coöperation by the Health Division was facilitated by a parallel organization, the Health Commission of the Chinese National Relief and Rehabilitation Administration. In the 15 regions, the UNRRA personnel coöperated with their Chinese opposites in a combined effort to restore public health and medical activity to at least pre-war effectiveness as rapidly as possible.

Several hundred doctors and dentists found among the displaced persons were asked by UNRRA to help care for their fellows in the assembly centers. For example, in the British and United States occupation zones of Germany at the end of July, 1946, there were 152 dental clinics staffed by 311 dentists, nearly all displaced persons.

Certain principles determined whether a country desiring assistance needed a Mission and health services. Such assistance was available to invaded countries seriously damaged, and finally liberated from the enemy, which did not have enough foreign exchange to purchase the imports they needed. This was the case with Greece, Poland, Czechoslovakia, Yugoslavia, Albania, Ethiopia, China, Byelorussia, and the Ukraine.

Work was done also in ex-enemy countries under conditions determined by the UNRRA Council. These were Italy, Austria, and Hungary. In Germany, UNRRA assistance was given solely in the care of displaced persons. Limited assistance was given to the Dodecanese, Finland, Korea, and the Philippines.

In the assisted countries, the health staff, headed by a chief medical officer, is an integral part of an UNRRA Coun-

try Mission, and is under the overall direction of the Chief of Mission and his deputies. For technical guidance and general health policies there is, nevertheless, a close dependence on regional offices and headquarters. The international professional health staff in a Country Mission varies from one medical officer in Czechoslovakia and the Ukraine, for example, to 174 professionally trained people in China. However, what we have come to think of as a "standard mission," has at least a chief medical officer with public health training, a chief public health nurse, and a chief sanitary engineer at Mission headquarters, with field personnel in the districts assigned according to need. The large staff of 640 persons in Germany is occupied only with the care and health protection of displaced persons. Similarly engaged are 55 persons in Austria (29 physicians, 26 nurses), 5 in Italy (3 physicians, 1 sanitary engineer, and 1 nurse) and all 17 of the persons in the Middle East.

ORIGIN AND FUNCTIONS OF THE HEALTH DIVISION

When the future historian evaluates the work of UNRRA's Health Division, he will probably attribute greater significance to its service in bridging the war-caused gap in the evolution of international health organization than to its relief operations of a purely emergency nature. Many of the national health departments, on which the world health structure must rest, were inhibited or broken by the most widespread and destructive of all wars. There was an unprecedented shortage of materials, apparatus, transportation, communications and buildings essential to the protection of health and the maintenance of medical care. There was, in addition, disorganization, loss of trained personnel, and isolation from the newer health knowledge. The international bodies such as the League of Nations

Health Organization and the International Office of Public Health in Paris, to which the affected national health departments would naturally turn for guidance and leadership, were cut off from most of their field of activity and were largely prevented from functioning. The International Health Division of the Rockefeller Foundation had been forced to terminate most of its activities in Europe, and had as a result deflected more of its attention to South America. The Pan American Sanitary Bureau, operating only in the Americas, was less disturbed. The experiences of these organizations, and the experts they had trained, were most valuable for the restoration of health departments in the liberated countries and in carrying forward the health work of UNRRA.

To face the challenging situation, UNRRA's Health Division was created in December, 1943. Forty-four nations had signed an agreement on November 9 establishing the United Nations Relief and Rehabilitation Administration. The Health Division started operations shortly after the first Council session, meeting in Atlantic City, had laid down in detail the purposes and objectives of the new agency, and had given it the necessary framework of instructions and authority.²

The functions of the Health Division may be summarized briefly as follows:

1. Assistance to national health authorities
 - a. in the prevention of war-engendered epidemics,
 - b. in the rapid restoration of national health departments,
 - c. by assignment of technical staff for consultation and coöperation,
 - d. in determining the requirements in medical and sanitary supplies to replace losses through destruction, looting, and the cutting off of sources, and in coöperating with UNRRA's Bureau of Supply in related technical matters of procurement and distribution.
2. Revision and administration of international sanitary conventions for maritime and aerial quarantine, as applied to signatory mem-

bers of the United Nations, and the carrying out of the specific duties imposed on UNRRA by the revised conventions.

3. Provision and technical supervision of medical and sanitary personnel for the care and health protection of persons displaced by war wherever UNRRA has responsibility for them in assembly centers, or camps, or during travel back to their countries.
4. Training of professional health and medical personnel of the assisted countries, in preparation for relief and rehabilitation work, through study fellowships in foreign lands and by supplying teachers and lecturers for courses in the assisted countries.

PREVENTION OF EPIDEMICS

The great wars of history have been accompanied and followed by sweeping epidemics, usually directly related to the devastation and hardship. In the recent World War, since the destruction was more widespread than ever before, the greatest catastrophes were to be expected. Multitudes of people were being driven from place to place. Thousands were crowding into makeshift dwellings. Scarcity of food, clothing, medical care, and even of pure drinking water was almost universal. And most of the health departments that had survived the war had been completely disrupted and so largely deprived of necessary personnel and supplies that they were quite ineffectual.

The only hope of avoiding major health disasters lay in the advances in medical science made since the previous World War and in early organization to apply this new knowledge effectively.

Appreciating the appalling risks to world health, the Council of UNRRA gave the Health Division a wider mandate with regard to epidemic prevention than in its other fields of activity. It authorized measures to control epidemics not only in liberated areas but also in enemy and ex-enemy countries with the purpose of preventing the spread of such epidemics to United Nations areas or to displaced persons of United Nations nationality.

Of the war-engendered epidemics to be expected, the one that presented the most alarming threat was typhus fever. Consequently, the Health Division felt the highest degree of responsibility for curbing it. Without control, widespread epidemics of typhus were inevitable. With control, safety was possible because of the effective new weapons which had been developed against the disease. UNRRA was in a position not only to secure and distribute vast quantities of DDT delousing powder, but through its field staff it could give directions as to the method of application.

The results have been highly gratifying. No great runaway epidemics of typhus have occurred as the result of the recent war. Credit must be given first to those who devised the practical and effective methods of delousing fully clothed persons by powdering with DDT. The Bureau of Entomology of the U. S. Department of Agriculture, the International Health Division of the Rockefeller Foundation, and the United States of America Typhus Commission all contributed invaluable evidence obtained through experiments and field trials. Before UNRRA had free access to some of the critical areas, the occupying armies, the U. S. A. Typhus Commission, and the International Red Cross here and there helped the local health authorities to keep the situation in check. As soon as the shipping lanes were cleared, UNRRA dispatched thousands of tons of DDT powder and many hundreds of dust pumps. UNRRA staff was sent in to help organize control and to give instruction in methods. A limited amount of typhus vaccine was supplied also but it was not used on a large scale in the general population, and therefore played only a secondary rôle. The size of UNRRA's effort is disclosed by the large amount of 10 per cent DDT delousing powder which is being distributed to the various countries, as shown in the first column of

TABLE 3

Total Program for Shipping DDT, by Recipient Countries

Recipient Country	For Typhus Control	For Malaria Control		
	10% DDT Powder	20% DDT Solution	26% DDT Solution	100% DDT Powder
	In Pounds	In Gallons	In Gallons	In Pounds
Albania	198,100	39,000	50,000	24,000

Totals	6,786,481 (3,393 tons)	404,204	932,000	1,452,075

Table 3. The other columns showing the amounts of DDT being shipped for use in malaria control will be referred to later. A single dusting of one person requires about 2 ounces of the 10 per cent DDT delousing powder, and it is effective for several weeks.

Probably the most practical estimate of the general results of the campaigns against typhus can be obtained by comparing the typhus incidence in Poland in the years 1919 and 1920, immediately after World War I, with the available figures for part of the corresponding period of 1945 and 1946, after World War II. This is done in Table 4 and Chart 1.

In 1919, the maximum monthly inci-

dence was 33,929 cases in May. For 1945 our reported figures began with April, and the comparable peak seems to have been reached also in May with 2,987 cases, or less than one-eleventh as many as in May, 1919. In 1920 and the early part of 1946, the corresponding maximum figures, both of them in January, were 34,530 and 1,235, giving a ratio of approximately 28 to 1. The data for 1919-1920 are for Congress Poland and Galicia only, while those for 1945-1946 relate to the present territory of Poland, including the three former German provinces which came under Polish administration in September, 1945. Eastern Galicia is therefore excluded in the later period, but Poland,

TABLE 4

Typhus Fever in Poland, 1919-1920 and 1945-1946

December	18,333	4,576	682

CHART 1—Typhus fever incidence in Poland after World War I in comparison with the incidence after World War II

west of the German frontier of 1914 is included, which makes the two sets of figures fairly comparable. Moreover, the differences observed in the comparisons are so great that we are not attempting here to make allowances for changes of area or population. It is evident from the chart that typhus in Poland is being conquered and that the war emergency with respect to this disease is over. In fact, we are given hope that Poland could exterminate typhus before long by the modern methods which have been introduced. This result could be hastened by international planning with participation by Poland's neighbors as well.

A flare-up of typhus fever in Yugo-

slavia was also to be expected, for it was in Serbia that the great epidemic of 1915 occurred early in the previous World War. During that visitation, over 150,000 people died of typhus within a period of 6 months, and the daily admissions for typhus to military hospitals alone rose to the staggering height of 2,500. Nothing comparable was permitted to occur in the recent war, although the disease was epidemic in Croatia and Serbia before effective control could be initiated. The U. S. of America Typhus Commission was invited early to Yugoslavia to help control typhus. The Commission organized control by DDT dusting and vaccination and trained many persons in the

methods. Later UNRRA took over and continued to advise and to provide the necessary supplies. Typhus in Yugoslavia is steadily responding to control. There were about 50,000 cases in 1945, but only 3,000 in the first half of 1946.

The same rosy picture cannot be painted for another serious preventable disease. During my visit to Poland in November and December, 1945, I was astounded at the amount of typhoid fever then present. It was being largely attributed to the great amount of migration and to contact between cases. Unfortunately, we had no new techniques, comparable to the use of DDT in a dust gun, that could be used for combating epidemics of typhoid. Since then the Health Division has assigned

two sanitary engineers to its Poland Mission in the hope that they can assist the trained sanitary engineers of the Ministry of Health in discovering and correcting some of the responsible conditions in the post-war environment.

In Table 5 and Chart 2 is shown for comparison the monthly incidence of typhoid and typhus fevers from April, 1945, to August, 1946. The great seriousness of typhoid and the present low incidence of typhus are clearly shown. The typhoid fever maximum in October, 1945, was 17,629 cases and the peak in May of the same year for typhus was only 2,987 cases. The three former German provinces now under Polish administration are included only from September, 1945. Later returns show

* Provisional figures

that typhoid seems definitely to be coming under control.

The war and post-war conditions that brought a marked increase in the prevalence of typhoid fever in countries of continental Europe would have spread cholera also, had it not been completely absent. In fact, the disease had not extended west of Iran since 1931. In China, on the other hand, cholera is endemic and was quite active in the summer season of 1946.³ UNRRA was first called on for emergency help in fighting cholera in June of the previous

year when an epidemic was developing in Chungking. An UNRRA team of 7 physicians and 2 sanitary engineers, with 6 tons of needed medical supplies, was flown to India and over the Hump to that city. Unfortunately, one installment of the supplies was lost over the Himalayas. The team took part in the control of the epidemic and the care of the sick.⁴

Early in March of this year (1946), I saw in the Contagious Disease Hospital of Canton the first five cases of cholera of the recent epidemic. Subsequently, other cities of China were involved successively. The experience of the larger ones is shown in Table 6. By mid-summer, cholera became active also in southern Manchuria, where it flared up in numerous localities. In July alone, 11,910 cases and 4,697 deaths were reported from 26 cities and 2 rural areas of Manchuria.

Assistance to the Chinese authorities in the control and treatment of cholera has been promptly given by the medical staff of UNRRA. Cholera vaccine for mass immunization, and even calcium hypochlorite for water purification, were flown to Canton early in its epidemic. Since then several emergency shipments of material necessary for fighting cholera and for treating the sick with intravenous salt solution and plasma have been sent by air directly to China from

Toledo, Ohio. In Shanghai, two million cholera vaccinations had been performed by early July and this may have been one reason that the epidemic was losing momentum by the middle of that month. Investigations in connection with the cholera epidemics in Canton and Shanghai were carried out by an epidemiologist of the China Office.

Plague was almost completely kept out of the European post-war picture. It gained entry to the port of Taranto in southern Italy when the disease was present in the island of Malta. From September 3, 1945, to October 25, there were 25 cases in Taranto with 12 deaths. An anti-rat campaign was initiated. All the premises in the infected area were sprayed with 5 per cent DDT in kerosene to kill the potentially infected fleas, and about 20,000 workers were dusted weekly with 10 per cent DDT powder. UNRRA, as part of its coöperation, made available the advice of an expert on rat extermination. There was no spread to other cities.

In China, plague was a greater problem, but there was no really extensive epidemic after the country was liberated and opened to UNRRA. Since then, the focus centering in Fukien Province has been active.⁵ In the early months of 1946, there was much concern over reports from Mukden of pneumonic plague in Manchuria. There were 39 cases with 36 deaths, and the recovery of 3 was attributed to treatment with sulfadiazine. This small outbreak stopped abruptly, but there were 13 additional fatal cases of plague early in March about 70 miles from Mukden. The National Health Administration is continuing the study and control of plague in the Fukien area, using supplies sent by UNRRA, such as plague vaccine, sulfadiazine, DDT for killing fleas, and poison for rats. UNRRA has also assigned to this work a team consisting of an epidemiologist, an entomologist, and a sanitary engineer.

Since Kala-azar is a disease transmitted by a bloodsucking fly, a species of *Phlebotomus*, it can hardly be regarded as a result of the war, although aggravated by the resulting neglect. There are about three hundred thousand persons near the Yellow River in Honan, Kiangsu, and neighboring Provinces, who have this serious disease in acute form and urgently need treatment. They have been cut off by the war from the source of supply of the antimony drugs that would cure them. UNRRA's Chief Medical Officer in China has urged that for the time being these drugs be given priority over all other medical supplies in shipments to China. Unfortunately, the world's entire manufacturing capacity for antimony drugs is not enough to fill the needs promptly and it is proving necessary to bring about the expansion of the facilities for production. The medical officers of UNRRA and CNRRA are not satisfied to limit their program to treatment alone and are hoping to use DDT supplied by UNRRA in an attack on the *Phlebotomus* responsible for transmitting the disease, thus, initiating a program of real prevention. This may not get into full swing until more is known of the insect and its habits.

For several years, diphtheria has been the leading epidemic disease in a large part of Europe.⁶ Great quantities of diphtheria toxoid for immunization and antitoxin for treatment are being shipped by UNRRA to the assisted countries. The amount of diphtheria toxoid in the supply program is 6,015,960 ml., or enough to immunize 2,406,384 persons. Diphtheria antitoxin is being supplied up to a total amount of 5,167,080,000 units. Material for the Schick test also is provided.

CURBING ENDEMIC DISEASES

The incidence of tuberculosis has gone up so high in the war-ravaged countries that this disease presents a serious and

lasting post-war problem, as it did after the first world war. Tuberculosis experts on UNRRA's staff have made surveys in many countries, using mass radiography, have analyzed the problem, have given advice as to the control of the disease, and have assisted in restoring and correcting the institutions for the tuberculous. Such a program has reached an advanced stage in Greece, for example, but is still far from complete.⁷ The Greece Mission has a Chief Tuberculosis Consultant and under him are five area teams, each consisting of a tuberculosis specialist, nurses experienced in this disease, a radiologist, and a clerk. These teams travel from village to village, examining people to determine the extent of the problem, inspecting sanatoria and helping set up clinics, advising the authorities, and training technicians in the use of radiographic units. Some 70,000 persons have already been examined by mass miniature radiography. When tuberculosis has been dependably diagnosed, an effort is made to arrange for supplementary rations. Interest has been stimulated, an advisory National Tuberculosis Council has been organized, and there is large-scale coöperation from voluntary agencies. Supplies from UNRRA have been given to nearly every sanatorium and dispensary in Greece. Such supplies range from bedsteads and x-ray apparatus to drugs and special surgical instruments. All this is of great assistance to the governmental health authorities, who are facing an otherwise insuperable problem, for in Greece as in the other liberated countries the surveys reveal a marked increase in tuberculosis.

The results of the tuberculosis survey in Poland have been published by an UNRRA specialist.⁸ He reports that the restoration of the sanatoria is going ahead and that much equipment has come from UNRRA. In Italy, the war against tuberculosis is benefitting not

only from the UNRRA surveys and equipment but also from generous allotments by the government from the proceeds of sales of UNRRA supplies.

Wars produce a marked increase in venereal diseases, and World War II was no exception. Fortunately, treatment has become much more effective in recent years, and the knowledge of methods of control has also advanced. UNRRA has supplied large quantities of drugs useful in treating diseases of this class and has supplied information about their use. A specialist in venereal disease control and treatment has been attached to the UNRRA Mission in Poland, and several of the other medical officers possess special knowledge and experience in this field.

In the treatment and control of many diseases beside those here mentioned, there is a growing dependence on specific and effective drugs. Many of the older effective drugs were not generally available in the occupied countries during the war. The more recent ones were not known when the war started and had not been brought in when UNRRA began operations. The physicians and health officers were eager to get the newer drugs and biologicals and information regarding their effectiveness, safety, and methods of use. To illustrate the quantities in which drugs were supplied by UNRRA, I shall give a few items from UNRRA's total procurement program for the assisted countries: penicillin, 809,550 million units; insulin, 663,690 thousand units; various sulfa drugs, 1,074,265 lbs.; acetyl-salicylic acid (aspirin), 1,207,000 lbs.

CAMPAIGNS AGAINST MALARIA

Several of the liberated countries assisted by UNRRA have suffered long and intensely from malaria. The war increased the problem by disrupting drainage systems, depriving the public of suppressive and curative drugs, and in general interrupting the existing

activities against malaria. An extraordinary opportunity for widespread and systematic malaria control presented itself to the Health Division after these countries were liberated, and no time was lost by the sanitary engineers of the Division in organizing the field operations. The new methods which made cheaper and more effective control possible were the residual spraying of houses with DDT solution to destroy the adult mosquitoes and the distribution of the same insecticide from hand pumps or airplanes on water surfaces to kill the larvae.

The largest of the campaigns planned by UNRRA personnel in cooperation with the governmental health authorities were in Italy and Greece. The results were highly successful and the procedures were most popular. Not only did mosquitoes diminish and malaria almost disappear, but there was also a heavy incidental mortality among houseflies, bedbugs and fleas.

The campaigns in Italy were carried out with the approval of the High Commissioner of Hygiene and Public Health and with the cooperation of the Provincial Medical Officers and the anti-malaria committees. The program depended mainly on residual spraying. It began in Sicily in January, 1946, and was continued first in Frosinone, then in the highly malarious strip of the south coast of Central Italy, and finally in the delta of the River Po. In the entire operation, the Italy Mission of UNRRA supplied technical supervision through its engineers. Moreover, it furnished 21 vehicles, 50 tons of pure DDT, 216,000 gallons of kerosene, 8,000 gallons of concentrated DDT emulsion, and the necessary sprayers. Twenty-five to 150 persons were engaged in spraying in each of the areas treated. These areas had an extent of 1,890 square miles and included about one-third of the total malarious territory of Italy, excluding Sardinia. The num-

ber of houses sprayed was 50,000; other structures similarly treated numbered 143,000; and the total area of internal wall space sprayed was 31,405,049 square meters. The good results gave rise to the prediction that a similar scheme of operations applied to all the malarious areas in future years could reduce malaria until it ceased to be a problem.

The preliminary work of an attempt to eliminate malaria from Sardinia by exterminating the anopheline species responsible for transmission has been started. This will be a joint project of the Government of Italy, the International Health Division of the Rockefeller Foundation, and UNRRA. The International Health Division is supplying the directing scientific staff, the Government is allotting funds for expenses from the proceeds of the sale of UNRRA supplies, and UNRRA is making available motor equipment, DDT, and other materials. Encouraged by the successes in eliminating *Anopheles gambiae* from Brazil and southern Egypt, the directors of the project are hopeful that a similar drive on the European anophelines responsible for transmitting malaria in this isolated island will result in their complete and permanent elimination.

The campaign against malaria in Greece was nation-wide from the start, and was planned and directed by the Chief Sanitary Engineer of the UNRRA Mission in cooperation with the Greek health officials. The methods all involved the use of DDT and included residual spraying of houses, distributing an oil solution of this larvicide by hand pump on small mosquito breeding places near malarious villages, and applying 20 per cent DDT as a thermal aerosol to large and inaccessible breeding places from 10 specially equipped airplanes. It is estimated that approximately 300 tons of DDT, in terms of the pure chemical, will have been used during

1946, or most of the supply designated for Greece in Table 3. For administrative purposes Greece was divided into 11 regions, in each of which there were an UNRRA medical officer and a sanitary engineer who worked in close co-operation with a Greek Government malariologist and a sanitary engineer. Seventeen planes were supplied by UNRRA, of which 10 are used in the regions. The other 7 are used for training pilots, for inspection trips, and as a source of replacement parts. Each plane can treat 17 acres per minute, and approximately 285,440 acres of mosquito breeding surface have been treated, counting each area every time it is gone over. The interval between treatments is about 15 days. This amount of operation by airplanes has required 17,840 gallons of 20 per cent DDT. Residual spraying has been applied to over 4,000 villages and towns to approximately 300,000 houses, stables, and other diurnal resting places for mosquitoes. The results of the combined methods seem to have been excellent and the people are enthusiastic. The fall survey should give a more accurate estimate of the reduction in malaria and its mosquito vectors.

The malaria experience of the Health Division seems to have demonstrated that it has at last become practicable and economical to control malaria on a national scale.

VARIOUS OTHER ACTIVITIES

It is natural that nutrition should be a prime interest of the Health Division in view of UNRRA's great responsibility to supply food under its relief program. Medical Nutrition Consultants and Dietitians of the Health Division made many surveys of the physical condition and diets of population groups suffering from food deprivation. Their primary duty was to report on the current state of nutritional health and to advise on matters of food and nutrition. The de-

tailed survey for Italy has already been published.⁹ Some of the specialists made observations of acute starvation in Germany, Holland, and China. One of them organized a group of about 100 medical students and directed their efforts to save starving inmates of Belsen Camp by scientific methods.

In Italy, in addition to the study cited above, there was an extensive survey by the Italian Medical Nutrition Mission sent out by the Unitarian Service Committee and the Congregational-Christian Service Committee with the coöperation of UNRRA. They undertook to find out, by experimental feeding of malnourished children, what important food elements were most lacking, and to advise UNRRA as to needed supplements to the diets being supplied to hospitals. This team of medical scientists and laboratory technicians worked from April, 1945, to March, 1946, in six different parts of the country. It examined 28,651 persons, and gave service to 1,984.

In China, five CNRRA-UNRRA nutrition teams investigated the famine areas to determine their nature and extent. The results confirmed the existence of acute famine and general low caloric and protein intake, especially in Hunan Province. As a follow-up, special emergency supplies, including vitamin products and serum protein, were flown in from Shanghai. In the meanwhile every attempt was being made to hasten the sending of quantities of food.

The general conclusions in the reports from all countries investigated seemed to be that 'various degrees of underfeeding were encountered, sometimes actual starvation, but that frank deficiency diseases, such as scurvy, pellagra, rickets, and beriberi, were less frequent than would be expected. Of these diseases, rickets is the one most frequently encountered.

Consultants in maternal and child

health have made surveys and advised the governments and Missions. A school feeding program is a prominent feature in the Greek program, and the preschool children also receive attention.

Dental consultants have surveyed the needs in the several countries for dental care and have given special attention to the organization of dental services in assembly centers for displaced persons. The dental consultant attached to the European Regional Office has given lectures and demonstrations to the local dental profession.

The medical and surgical side of the rehabilitation of the disabled is a responsibility of the Health Division, although the other aspects have fallen to welfare workers and voluntary agencies. In Athens, a rehabilitation center has been sponsored by the Greek Government, UNRRA, and the Near East Foundation. The Health Division has provided an orthopedic surgeon consultant. Artificial limbs and materials for local manufacture and repair are being supplied.

A series of UNRRA facio-maxillary surgery teams was sent to Yugoslavia from London. The first, consisting of 6 persons, arrived near the end of 1945. These teams demonstrated the latest techniques for correcting mutilation, and trained local surgeons and nurses.

In many projects which have been mentioned voluntary agencies took an effective part. This was especially the case in the work with displaced persons in the Middle East Camps and in Germany. Voluntary agencies provided health personnel numbering about 500 for work in Europe and an additional number for China. They also contributed medical supplies for devastated areas.

INTERNATIONAL SANITARY CONVENTIONS

The occupation of France isolated the International Office of Public Health and interfered with its administration of the International Sanitary Conven-

tion of 1926 (Maritime) and the International Sanitary Convention for Aerial Navigation of 1933. This left international quarantine in so serious a predicament that something had to be done about it. To meet the situation UNRRA's Standing Technical Subcommittee on Health for Europe promptly appointed an Expert Commission on Quarantine to draft international sanitary agreements of an emergency nature.¹⁰ The Commission later submitted to the Standing Technical Committee on Health in Washington drafts for two conventions, modifying and modernizing the existing ones. Each draft provided that UNRRA should carry out the duties previously assigned to the International Office of Public Health in Paris. After some modification in the light of the comments of member governments, UNRRA approved the proposed conventions and they were opened for signature at the State Department of the United States of America, the depository of the conventions. The required number of signatures was reached on January 15, 1945. The two conventions of 1944 came into effect on that date and have been administered since then by the Health Division from the Headquarters of UNRRA in Washington, with the European Regional Office in London acting as a branch for the regions in its sphere—Europe, Africa, and the Middle East. Headquarters makes notifications directly to China, Australia, New Zealand, Canada, and the United States, and through the Pan American Sanitary Bureau to the other American republics.

At Headquarters, the Division is publishing the semi-monthly *Epidemiological Information Bulletin*, carrying disease reports and epidemiological analyses. The European Regional Office is bringing out an additional fortnightly *Bulletin of Communicable Diseases and Medical Notes* for distribution to the governments in its area. A small *Weekly*

Epidemiological Bulletin is also sent out from London in printed form to give prompter information regarding the appearance and movements of serious diseases. Most of the reports to and from both offices with regard to pestilential diseases are transmitted by cable.

The duties imposed by the 1944 convention for aerial navigation include the delineation of the yellow fever areas of the world for purposes of quarantine, and also laying down standards for yellow fever vaccine and designating institutes approved for carrying out tests of the vaccines. These special functions have been performed by an Expert Commission on Quarantine appointed by the Standing Technical Committee on Health. In 1946 the Commission carried out an exhaustive test of the immunizing properties of the Dakar yellow fever vaccine administered by scarification, alone or mixed with smallpox vaccine. The Commission recommended that the method be certified as acceptable in the issuance and recognition of international certificates of inoculation.

All the duties imposed on UNRRA by the International Sanitary Conventions of 1944 and the Protocols prolonging them were of temporary and emergency nature. They will, therefore, be transferred to the Interim Commission of the World Health Organization on December 1, 1946, as agreed in letters exchanged by Mr. F. H. LaGuardia, Director General of UNRRA, and Dr. G. Brock Chisholm, Executive Secretary of the Interim Commission. Although the Central Headquarters of the Interim Commission will remain in New York, according to latest advice, the Epidemiological Office in charge of the administration of the conventions will be in Geneva.

The last issue of the *Epidemiological Information Bulletin* will appear on December 15. The two complete volumes will form a valuable compilation of statistics for reference with

regard to the war and post-war period. Complete sets can still be made available to libraries and institutions requiring them.

MEDICAL CARE AND HEALTH PROTECTION OF DISPLACED PERSONS

In May of 1944, the responsibility for the six refugee camps in the Middle East was assumed by UNRRA. At the end of March, 1945, there were about 40,000 displaced persons in these camps, including nearly 15,000 children. The health staff contained specialists in nutrition, dietetics, tuberculosis, maternal health, child health, public health nursing, and sanitary engineering, and also clinical doctors and nurses. Since then, most of these refugees have been repatriated. Each returning group was accompanied to its destination by an UNRRA repatriation team, including a doctor and two nurses. There now remains only one of these camps, at El Shatt, with a few hundred refugees.

A problem of greater magnitude was presented by the displaced persons under UNRRA care in Germany, Austria, and Italy. At the end of May, 1946, there were 826,580 such persons in assembly centers in the three countries. The Health Division was responsible for recruiting the necessary health personnel and giving technical supervision. An extensive immunization program was undertaken. In most of the assembly centers a large part of the medical, dental, and nursing services was provided by professional persons found among the displaced persons, with overall supervision by UNRRA staff. Dispensaries have been set up and arrangements made for hospital care, mostly in local institutions with UNRRA supervision. Nurses among the displaced persons are being given refresher courses, and other women are being trained as nurses' aides, in order to replace UNRRA nurses as they are withdrawn. The health conditions in the

assembly centers have been on the whole quite satisfactory.

INSTRUCTION OF HEALTH PERSONNEL

In the long run much more is gained by training the nationals of a country to do their own health work than by introducing relays of foreigners to do it for them. For training for participation in relief and rehabilitation work in the field of health, UNRRA brought many Fellows from the assisted countries to educational centers of the United States and of the United Kingdom and other countries of Europe, and arranged for their studies and tours of observation. The first group consisted of 12 technical experts from China who came to the United States in 1944. After their return, many of them assumed key positions, becoming, for examples, Head of the Medical Commission of CNRRA, Director of Medical Supplies of this Commission, Director of the Anti-Epidemic Prevention Bureau of the National Health Administration, Director of Hospitals and Health Centers of the NHA, and Head of the Department of Sanitary Engineering in the National Institute of Health.

In 1946 a new program of UNRRA fellowships was offered, with 44 falling to the Health Division. The recipients included physicians, nurses, sanitary engineers, radiography technicians, and students of penicillin production. They received their instruction in the United States, Canada, the United Kingdom, Sweden, and Switzerland. In 1946 there was set up also a special Nurse-Teacher Fellowship project. The Fellows were carefully chosen graduate nurses interested in teaching, 121 in number. Twenty-seven came from Italy, 20 from China, 18 from Czechoslovakia, and 19 from Poland. This group received its special training in institutions of the Department of Hospitals of New York City, with brief observation trips to other centers.

Twenty nurses from Austria and 17 from Greece were similarly trained in London.

In another of the training projects of the Health Division, medical teaching missions were sent to Poland and Czechoslovakia to visit the medical centers and bring the newer knowledge of the war years to the medical and dental professions. They had been almost completely isolated during the war years. The lecturers were provided for Poland and Czechoslovakia by a voluntary agency, the Unitarian Service Committee, with the coöperation of UNRRA. In Czechoslovakia, 14 lecturers from 8 universities began their tour in Prague and then went to Moravia and Slovakia, giving lectures and demonstrations in all 6 of the medical schools of the country. In Poland, the team of 7 lecturers included 2 dentists. It visited the principal cities, giving lectures to professional groups and students and leading discussions. Several lecturers had previously been sent to Poland by the Health Division, beginning in November, 1945, to get this valuable and much appreciated teaching started.

In 1945 a team of 11 teachers was sent to China to start a medical training program in conjunction with the National Institute of Health. The early courses in Chungking, with a total enrollment of 258 students, covered public health administration, medicine, surgery, gynecology, tuberculosis, public health and hospital nursing, maternal and child health, and bacteriology. A second series of courses was given in Peiping in the spring of 1946, with 136 students. In the interval between the two series, the teachers gave refresher courses to local medical societies and schools in Shanghai, Nanking, Peiping, and Tientsin. More recently they were assigned to medical schools in Peiping, Nanking, Chengtu, and Shanghai. Other technical personnel of the Health Division working in China have co-

operated in short courses or lectures for laboratory technicians, dentists, medical students, nurse trainees, field workers in rodent control, and medical supply officers.

The UNRRA nurse consultants in several countries, and especially in Greece, worked with the local nurse leaders in reopening and reorganizing schools of nursing and giving refresher courses in public health.

The Health Division's project in Ethiopia is essentially an attempt through teaching to take the first steps toward creating an indigenous medical and nursing profession. In this way, the ground work will be laid for a future public health service, and meanwhile the people will benefit from service of steadily rising quality. Courses for medical "dressers" and for sanitary inspectors are being conducted, and assistance is being given to the hospitals and clinics essential to this educational effort.

HANDING OVER TO A PERMANENT ORGANIZATION

The activities of UNRRA as here outlined are coming to an end, but many of the needs will continue and great opportunities stand open. So UNRRA has made its plans, in conference with officers of the Interim Commission of the World Health Organization, to hand over a number of its functions, on January 1, 1947, for Europe and Africa, and on April 1 for the Far East. The activities suggested for transfer to the Commission are (1) fellowships and teaching, (2) the project in Ethiopia, (3) tuberculosis, (4) malaria, (5) missions of experts to countries with special needs, and (6) the administration of these functions. To make possible the continuation of this work in the present UNRRA-assisted countries for approxi-

mately one year, after which the World Health Organization should be fully established, the Central Committee has authorized the Director General of UNRRA to turn over \$1,500,000 to the Interim Commission. No supplement of the Commission's budget will be needed when the administration of the sanitary conventions is transferred on December 1.

The temporary Health Division will soon be giving place to a permanent and growing international health organization. On relinquishing their duties, the officers of the Health Division hope that their efforts have accomplished more than the alleviation of ravages of war. The World Health Organization should make a quicker start and be able to see its way more clearly because UNRRA, at a most difficult time, attacked the problems of international health.

Report of the Chairman of the Executive Board of the American Public Health Association to the Governing Council 1945-1946

THIS was the year when the membership of the Association went over the 10,000 mark. Many of my colleagues would feel, perhaps, that this is a less dramatic statement with which to open an annual report than might be made about any one of half a dozen events of an especially eventful year.

I hold, however, to the old-fashioned idea that in a democracy or in a democratic organization people are more important than happenings and that events have significance and meaning only as they are judged by their effects upon people.

Five years ago five thousand persons by the fact of their membership sanctioned what the Association is, what it stands for, and what it has done. Now as then sole compulsion to join this professional society comes from the voluntary urge of the individual to enter a community of persons with similar objectives and aspirations. But the urge is not translated into action unless it is rooted in the belief that the common cause is being advanced in a direction and by methods acceptable to the individual. Today twice 5,000 individuals sanction the Association's purposes and its program. Among them there may be healthy differences of opinion but there is no fundamental confusion. This is the perspective in which we attempt to assess what has been made to happen by the 10,000 men and women who are this organization.

Ours is a community of influence and

power. No one can scan the *Membership Directory* which has just been published, in which each of the 10,000 and more is listed and identified, without an awareness of the great strength which is there in total. The vast professional reservoir, this collective public health "know-how," cannot be matched anywhere in the world in a single organization. It is the Association's prestige. It is the Association's propulsion into a position of leadership as new vistas open before us. It is the reason it is entrusted with responsibilities which might conceivably be fulfilled under other auspices but without the authority the Association alone possesses.

These acquisitions to our joint resources and energies, which in essence is what the growth in membership over the past few years means, have had their effect in very concrete terms. The first consequence of a membership which has passed the 10,000 figure is the demand for more service from the Central Office. Simple mathematics show us that ten thousand members want more books, more *Journals*, more reprints, more information, more self-expression, more of everything on a sheer quantitative basis than 8,000 or 5,000. As a result the secretarial and stenographic force has been enlarged. A more subtle and more important consequence is that new projects have a way of being laid at the door of a going concern of proved power and effectiveness and

they require professional attention at headquarters. The expansion of professional staff has, therefore, been mandatory this year. Young, qualified persons have been selected for specific responsibilities as the Association has accepted more opportunities to be useful to public health workers, and through them, to the public.

In May an Engineering Associate was added to the administrative staff. Plans are now under way to secure an engineering field consultant. These two appointments recognize the importance of the engineer in public health programs and make his interests one of the paramount concerns of the Association at a strategic time. A medical vocational consultant on a full-time basis is in charge of the counselling and placement service. The Merit System Unit staff has been augmented by a field consultant with major experience in education and psychology. The Subcommittee on Medical Care has opened a Washington office with a technical secretary, a medical field consultant, and a research associate.

None of this strengthening of the Central Office staff could have been effected if the projects to which these new persons are attached had not commended themselves as worthy of support to foundations and other agencies. The Rockefeller Foundation has made possible the work of the Subcommittee on Medical Care. The National Foundation for Infantile Paralysis has provided the funds for the enlargement of the Merit System Unit staff, its officers realizing the value to their own objective—the elimination of poliomyelitis and the alleviation of its effects—of well trained, properly selected local and state public health personnel. It is for this reason that they have wisely provided funds for the extension of the services of the Merit System Unit to local health departments. The introduction of the engineering field consultant service has

come about by funds raised by the sanitary engineering profession itself on a matching basis with funds provided also by the National Foundation for Infantile Paralysis.

In a report in which expansion is the keynote, it is appropriate to acknowledge at the outset the generosity and confidence of these foundations and agencies for their contributions to the growing process. The Albert and Mary Lasker Foundation has provided funds for the Lasker Awards and their administration. We include in our appreciation others whose continued financial coöperation, in many instances over a long period of years, has sustained enterprises which have become part of the Association's permanent program. The patriarch among these is The Commonwealth Fund with its support of state studies for the Committee on Administrative Practice, and its continuation for the second year of support for the Accreditation project of the Committee on Professional Education. The U. S. Public Health Service and the Children's Bureau still stand behind the Merit System Unit. The former has provided the means through which the Association has been able to purchase expensive duplicating equipment, thus making the Unit's services more effective. It has also continued its support of the Vocational Counselling and Placement Service, now an important arm, organizationally, of the Merit System Unit with the vocational director serving both projects.

The W. K. Kellogg Foundation made available this year \$15,000 for the first National Conference on Local Health Units held at Ann Arbor under the sponsorship of the Association through its Committee on Administrative Practice, the University of Michigan, and the Association of State and Territorial Health Officers. The W. K. Kellogg Foundation, too, financed a meeting of the Study Group on Sanitation, looking

toward the development of an evaluation schedule on environmental sanitation for general use by health units. To the Milbank Memorial Fund and the National Tuberculosis Association we owe acknowledgment for funds given to the Subcommittee on the Hygiene of Housing; to the American Drug Manufacturers Association for moneys which promote activities of the Subcommittee on Evaluation of Administrative Practices, and to our Sustaining Members whose names we have featured in the new Membership Directory.

Ear-marked funds for special purposes plus the income from dues of 1,620 Fellows, 8,752 members, 36 Sustaining members, 26 affiliated societies, subscription fees from another 3,000 non-member *Journal* readers, the Association's business services such as advertising and exhibit space, books, and pamphlets have given us sufficient income for the adequate discharge of our old and new commitments. We are operating on an assured budget of approximately \$275,000, keeping our expenditures within it even in a year when anticipations of expenditures must be revised upward almost daily.

In acknowledging our appreciation for the substantial funds put at our disposal this year, I have named a number of the activities in which the Association has been engaged in 1946. The full record, embracing both old and new, is so diverse and comprehensive that all a report like this can hope to do, and remain within reasonable limits, is to summarize, interpret occasionally, and synthesize. In a field as broad as ours, where concern with every phase of public health is exercised by one or another of our nearly 200 organized groups, what is the process of selection and what the criterion of emphasis for the chronicler of the year's events?

Matters enter the blood stream of the Association through several avenues. One is via the Sections. Section ac-

tivity is revealed through the Annual Meeting program, through published reports, papers, and books. A new volume coming from the Laboratory Section which will soon be exerting wide influence is the Ninth Edition of *Standard Methods for the Examination of Water and Sewage*, published in cooperation with the American Water Works Association. It is on the press and will be available this year. We credit Dr. John F. Norton's patience, skill, and ability for its completion. The Section expects to take action during the Annual Meeting upon the text for the Ninth Edition of *Standard Methods for Dairy Products*, representing a thorough revision of the earlier edition through the monumental efforts of Dr. Robert S. Breed and Dr. A. H. Robertson. After following the routines prescribed by the By-Laws for all standards to be issued in the name of the Association, the manuscript will be released to the Central Office for publication. The book will issue in 1947. In the discussion stage, and to be advanced by a session on the subject at the Annual Meeting, is a companion volume to *Diagnostic Procedures and Reagents*, on virus and rickettsial diseases.

The Dental Health Section is in sight of the goal toward which it has labored for two years—delivery of a set of manuscripts by some 18 qualified authors on the history, present status, and future of public health dentistry. The year's end will see the book completed. The Maternal and Child Health and School Health Sections have been exploring with their physician members the attitude toward the establishment of a qualification and examination by the American Board of Pediatrics, for pediatricians in public health. The Public Health Education Section has adopted regionalism as its keynote and is attempting to work out health education problems within the framework of

this philosophy. The Annual Meeting program, developed without wartime restrictions and accordingly more extensive than at any time in four years, and the contents of the *Journal* for the next several months will indicate other Section interests and accomplishments.

The Standing Committees initiate and carry on many of the activities in which we and they may well take pride. They have their own able spokesmen and their Chairmen will present detailed reports to the Governing Council for the first time in two years. I intend only to index for the record the important concerns of the Standing Committees, leaving it to their respective leaders to develop my chapter headings:

The Committee on Administrative Practice, Wilton L. Halverson, M.D., *Chairman*:

- Studies of state and local health administration
- The promotion of the evaluation process
- Health Practice Indices
- The Subcommittee on Medical Care
- The first National Conference on Local Health Units
- The evaluation of administrative practices
- Accident prevention
- Reciprocal sanitary milk control

The Committee on Professional Education, William P. Shepard, M.D., *Chairman*:

- The accreditation of schools of public health
- The Merit System Unit
- The Vocational Counselling and Placement Service
- Salaries of public health workers
- Educational qualifications of public health workers
- A specialty board in public health

The Committee on Research and Standards, Kenneth F. Maxcy, M.D., *Chairman*:

- The Standard Methods Committees
- The Committee on Hygiene of Housing
- Control of Communicable Diseases
- Control of Air-borne Diseases

The Committee on Eligibility, Vlado A. Getting, M.D., *Chairman*:

- Membership
- Fellowship
- Life Members
- Affiliated Societies
- Honorary Fellows

This is a calling of the roll of highly significant enterprises of which you will hear more from the Chairmen themselves.

Other of our activities have no structural or functional tie to any Section or any Standing Committee but cut across all organizational lines. There is, of course, the *Journal*. It has continued its series of special review articles started in 1945. In the 11 issues beginning with January, 1946, seven of these review articles have appeared. Three of them have dealt with relatively new scientific developments, Blood and Blood Derivatives, the Rh Factor, and the Position of DDT as an Insecticide; another summarized the school health services under governmental supervision in England and Wales. The *Journal* has kept its readers informed of the main developments in the World Health Organization. The November issue prints the W.H.O. Constitution in full and will carry the major address at the opening General Session of the Cleveland Annual Meeting by Dr. Parran and Dr. Boudreau which discusses the platform and purpose of the World Health Organization. Although the paper shortage still inhibits the *Journal* editors, each issue in 1946 has averaged twelve pages more than in 1945. The total circulation of the *Journal* remains at about 13,000, the cancellation of several hundred army subscriptions having been very largely made up by the increase in membership.

The authority and influence of the editorials by Professor C.-E. A. Winslow, the *Journal's* Editor, have been manifest in many ways. Requests have been widespread for permission to reprint *Panic or Reason in Dealing with Poliomyelitis?* in the August issue. Likewise, a Challenge to the Voluntary

Health Agency of October, 1945, continues to be widely read and discussed. The Association is indeed fortunate that in his retirement from the Yale Department of Public Health, Professor Winslow gives so freely of his talents of mind and pen to the *Journal* and the Association.

Made necessary by the increasing costs of publication, and amply justified by its increase in circulation, advertising rates in the *Journal* are about to be increased for the first time in 20 years. The *Journal's* circulation has increased by more than one-third in the past five years.

The work of the Committee on Constitution and By-laws, Dr. Edward S. Godfrey, Jr., *Chairman*, affects the entire Association in that it provides a sound basis upon which to build our organization. The committee, after two years of thoughtful study and examination, and with the approval of the Governing Council, is presenting at the Annual Meeting a revised Constitution and By-Laws. The document was published in the September *Journal* and the Fellows will vote upon the proposed amendments to the Constitution, and the Governing Council upon the proposed amendments to the By-laws. If they are accepted, we and individuals yet to share in the privileges and responsibilities of Association membership will be deeply in the debt of Dr. Godfrey and his committee members for a masterly recodification and clarification of a Constitution and By-laws which had become difficult of application and obscure as it was added to over the years in continuing attempts to democratize our procedures.

Other committees, like the Committee on Constitution and By-laws, are created by the Governing Council or the Executive Board for temporary or continuing purposes. A committee under the Chairmanship of Dr. George Baehr and including such outstanding

scientists and administrators as Thomas Francis, M.D., Hugh R. Leavell, M.D., Robert F. Loeb, M.D., Karl F. Meyer, Ph.D., Thomas Parran, M.D., Alfred N. Richards, M.D., James S. Simmons, M.D., and Ernest L. Stebbins, M.D., was appointed to determine the persons and organizations who should be honored for scientific and administrative achievement by the bestowal of the Lasker Awards.

From a long list of candidates, many of whom were proposed by the Fellows of the Association, the following individuals have been selected and for the reason mentioned to receive a cash award of \$1,000 and a statuette suitably inscribed:

- Dr. Carl Ferdinand Cori—For research in the rôle of anterior pituitary, insulin and hexokinase in carbohydrate metabolism
- Dr. Karl Landsteiner (posthumously), Dr. Alexander S. Wiener and Dr. Philip Levine—For research in the Rh factor
- Dr. John F. Mahoney—For research in the penicillin treatment of syphilis
- Dr. Alfred Newton Richards—For organization and administration of the Committee on Medical Research of the Office of Scientific Research and Development
- Dr. Fred L. Soper—For organization of eradication campaigns against yellow fever and malaria

The following groups have been cited for the reasons mentioned, the leader to receive on behalf of the group a statuette suitably inscribed:

- The Army Epidemiological Board—For distinguished service in the control of infectious diseases, bringing a permanent enrichment to medical science
- The Board for the Coordination of Malarial Studies—For accomplishments leading to a rational approach to the eventual solution of the malaria problem
- The Bureau of Entomology and Plant Quarantine—In recognition of distinguished service in the solution of problems involving the health and comfort of the Armed Forces, with particular reference to insect-borne diseases
- The National Institute of Health—In recognition of its fundamental contributions to the prevention and control of disease

The Northern Regional Research Laboratory—
For studies leading to the mass production
of penicillin

These Awards presented for the first time at the Cleveland Annual Meeting represent an expansion of the Association into a larger world. Public health is only just beginning to take note of the fact that future gains in national health and well-being must come in a new area, with a new group of persons, and with new techniques not yet crystallized. With infectious diseases of childhood and tuberculosis largely conquered, the new concern of public health is with the adult population—not only keeping it alive but, far more important, keeping its life active, socially useful, and personally rewarding. This is the significance of the Lasker Awards. The Association is indeed fortunate that the high purpose of its activities has inspired the Albert and Mary Lasker Foundation to make it the vehicle for a series of awards "to recognize achievement and to stimulate medical research, with special reference to those diseases which are the major causes of death."

Little that happens in the nation or in the world today concerned with public health escapes the Association's influence in one way or another. In the most important development of the year—the beginnings of the World Health Organization—two of the Association's Fellows represented the United States at the Technical Preparatory Commission in Paris in March. Eighteen Fellows and 22 Members were among the delegates, representatives, and advisers to the International Health Conference in New York, June 19 to July 23.

Dr. Thomas Parran was unanimously elected to serve as President of the Conference. The Conference adopted a constitution and provided for an Interim Health Commission until the

World Health Organization should be fully organized.

The breadth of the Association's interests and the depth of its influence are a poignant reminder of the giants we have lost during the year—Mazýck P. Ravenel, Milton J. Rosenau, and Waller S. Leathers. These three long-time practitioners and pioneers of public health and charter Fellows of the Association gave immeasurable service in making not only the Association the power that it is today but also in giving public health its current prestige. Dr. Ravenel brought the *Journal* to the status of a first class professional journal; Dr. Rosenau had two careers, each worthy of a lifetime, one in Harvard and one as the founder of the North Carolina School of Public Health; Dr. Leathers made a great contribution to medical education, and was adviser extraordinary to such agencies as the American Red Cross, the Commonwealth Fund, and many others. Each was elected President of the Association, but Dr. Rosenau did not live to serve his term. The war and the absence of an annual meeting in 1945 delayed by a year his elevation to the Presidency, to the great loss of the Association. Although there will be recognition of the passing of these three men in formal resolutions, I believe it fitting that our irreparable loss be recorded here as well.

We have said that happenings are significant only as they affect people. We do not always know how the things we are doing are influencing others, but not infrequently we have direct evidence of the impact practically of what we do academically. The *Evaluation Schedule* of the Committee on Administrative Practice, Dr. Halverson will tell you, is finding a wider acceptance and usefulness. Let me dramatize for you what this means with an illustration or two. Out in Kansas, where I'm told it's hard to get people to drink milk

and even harder to get it pasteurized, the Chamber of Commerce of a certain community became interested in the performance of its health department. A committee studied the *Evaluation Schedule* and found that the pasteurization of only 50 per cent of the community's milk supply brought it far down on the index scale for that activity. There resulted a community demand for a more extensive pasteurization program, a development the local health officer had attempted unsuccessfully through various other approaches.

Or consider a western city whose population more than quadrupled during the war production years, whose Negro population increased from two or three hundred to 15,000, and whose health department consequently found itself under the necessity of organizing to meet its expanded problems. An imaginative health educator used the *Evaluation Schedule* to teach the community about the self-evaluating process. Based on the *Schedule*, community committees set up an analysis of the health needs and resources out of which its present dynamic health program grew.

Another item that will be more fully discussed has to do with the extent to which the study and the basic principles of the Subcommittee on Local Health Units are affecting the philosophy and development of public health service. The framers of federal legislation have used its findings no less than the State Board of Health of Montana whose planning encompasses only about half a million persons. Such diverse national magazines as *Hygeia*, *The Survey*, and *Public Administration Review* have found this program germane to their separate interests.

Another example of the continuing services your Association renders to a wide and varied public may be found in the work of the Subcommittee on the Hygiene of Housing. There is wide-

spread and growing recognition of its housing appraisal method as a practical means for evaluation of substandard housing conditions and as a sound basis for shaping remedial programs. Substantial surveys by this method have been carried out in a number of cities of the United States, as Dr. Maxcy will report, but its influence does not end at our borders. Housing in Panama is being surveyed on the basis of the appraisal method. The survey, together with a summary of the appraisal methods, is being published in Spanish for distribution in Latin America at the instance of the Association in coöperation with Science Service.

Finally, for the sake of the future historian who will wonder how the Association took care of its elections and other legalities prescribed by its Constitution and By-laws in a year without an Annual Meeting—as 1945 was—and for which we had no precedent, it should be recorded here that the Executive Board invoked Article IV of the Constitution which provides that “all officers shall serve until their successors are elected and qualified.” This action held in office all elected and appointed persons whose terms would otherwise have expired in 1945. On the recommendation of the Committee on Constitution and By-laws, made after obtaining legal counsel, all offices which would have been vacated ordinarily in 1945 are vacated this year, making it necessary for the Fellows present and voting at the Cleveland Annual Meeting to elect 20 instead of 10 members of the Governing Council, 10 with terms expiring in 1948 and 10 with terms expiring in 1949. Under this decision there are 4 instead of 2 vacancies on the Executive Board to be filled. The Section Councils, the Committee on Eligibility, and terms of members of Standing Committees are similarly affected. This is a year in which twice the usual number of elections and ap-

pointments must be made. Both a President and a President-elect must be elected this year. Other responsibilities which must be carried out during the Annual Meeting bulk larger than in any previous year. The Committee on Eligibility will report on 216 applications for Fellowship—nearly 100 more than ever before—and 79 applications for Life Membership. Again the added responsibilities of the Central Office must be referred to—in connection with Fellowship applications more than 600 individual pieces of correspondence are in the files representing replies from references, and this checking of credentials is only a small part of the process.

To complete the story for the historian, let us say that for the first time we are using a voting machine for the election of members to the Governing Council instead of the familiar written ballots.

The future of our community is replete with immediate possibilities for usefulness. Our problem as an Association is no longer money, as it once was, but personnel and space. We have arrived at the stage where selection is the important thing—selection from among many things offered us for sponsorship. There are at least two large projects in new fields awaiting our decision at this moment, and there will be more before the year's end. In its 75th year, it may be said that the Association has just begun to roll and so have the public health professions which we represent. And as always it must be emphasized that "prime movers" are required to operate any machinery. Not the least of these are the Executive Secretary and his staff, to whom the entire membership owes a continuing debt for enthusiasm, intelligence, and efficiency.

ABEL WOLMAN, DR.ENG.

Public Health Degrees and Certificates Granted in the United States and Canada During the Academic Year, 1945-1946*

THE Committee on Professional Education presents its annual report of Public Health Degrees and Certificates Granted in the Academic Year, 1945-1946. In the current report all tabular data except two 5 year summaries are omitted. This is purely experimental to determine the demand for the material. Tables such as those published in previous years have been prepared and are available in mimeograph form on request from the offices of the Association. If the demand for them warrants it, they will again be published in the *Journal* in future years. There will be no lack of continuity in the data available for comparative purposes.

As formerly, the present report is based on returns from a questionnaire sent to the administrative officers of the schools offering graduate degrees. Their replies have been subjected only to statistical review. Only graduate students enrolled in courses leading to graduate degrees or certificates are included in the tabulation. Exceptions are public health nursing students, among whom are included those receiving Baccalaureate degrees or certificates in public health nursing. For figures on public health nursing students and degrees, the committee is indebted to the National Organization for Public Health Nursing, which has permitted their use in this report.

The report is based on 27 schools giving either or both public health and public health engineering degrees and 32 of 34 schools giving approved courses in public health nursing.

The first significant fact suggested by the reports of the academic year just passed is the continuing increase in both enrollments and degrees granted. The percentage increase is most marked among public health engineering, and least among public health nursing students. Enrollment of public health and public health engineering students together increased by more than a third over the previous year, a little less than one-third for the former, more than one-half for the latter. Since the low of 1942-1943 there has been an increase of nearly 90 per cent in enrollments (Table 1). Enrollment in graduate public health nursing courses is not reported.

The number of all students receiving degrees has increased by more than one-fifth since last year, nearly one-third for public health, two-thirds for public health engineering, and less than one-fifth for public health nursing students. Since the low point, both public health and public health engineering degrees have more than doubled. Public health nursing degrees on the other hand increased only one-third since the low point in 1941-1942, which was a

* For previous reports see *A.J.P.H.*, Vol. 35, p. 1311; Vol. 34, p. 1264; Vol. 33, p. 1430; Vol. 32, p. 1360; Vol. 31, p. 1306; Vol. 30, p. 1456; Vol. 29, p. 1338; Vol. 28, p. 863; Vol. 27, p. 1267; Vol. 26, p. 819; Vol. 25, p. 341; Vol. 23, p. 1124.

TABLE 1—ENROLLMENT IN GRADUATE PUBLIC HEALTH COURSES AND STUDENTS RECEIVING GRADUATE DEGREES OR CERTIFICATES, FIVE YEAR SUMMARY, 1941-1946

Academic Year	Enrollment			Students Receiving Degree or Certificates			
	Total	Public Health	Public Health Engineering	Total	Public Health	Public Health Engineering	Public Health Nursing
Total	2,746	2,254	492	5,925	1,258	249	4,418
1941-1942	629	466	163	1,077	269	89	719
1942-1943	387	323	64	1,057	159	24	874
1943-1944	460	396	64	1,119	207	35	877
1944-1945	540	462	78	1,204	270	38	896
1945-1946	730	607	123	1,468	353	63	1,052

year earlier than the low point for the other two groups.

It may be concluded, therefore, that the arrears in training piled up during the war years are beginning to be made up. In each group except engineering more degrees were granted in 1945-1946, than in any of the last six years.

As in previous years the professional background of the graduate students enrolled in public health courses was

reported. Physicians numbered 244, or two-fifths of the total, public health educators, 176, or less than 30 per cent. Each group is a larger percentage of the total than in the previous year.

The number of Master of Public Health degrees granted increased by more than one-half, due perhaps to the accreditation program which advises discontinuing the use of the M.S.P.H. degree. The number receiving the

TABLE 2—STUDENTS RECEIVING GRADUATE DEGREES OR CERTIFICATES—SUMMARY, 5 YEAR PERIOD, 1942-1946

Degree or Certificate	Total	1941-42	1942-43	1943-44	1944-45	1945-46
Total	5,925	1,077	1,057	1,119	1,204	1,468
Doctor of Public Health	40	12	7	10	8	3
Doctor of Engineering	5	2	1	2
Doctor of Science	24	17	1	3	..	3
Doctor of Philosophy	22	9	2	3	4	4
Master of Public Health	691	151	83	101	140	216
Master of Civil Engineering	16	6	3	5	1	1
Master of Science	118	28	13	29	17	31
Master of Science, Public Health	261	73	19	45	68	56
Master of Science, Public Health Engineering	11	2	1	4	..	4
Master of Science, Sanitary Engineering	23	4	2	1	..	16
Master of Science, Civil Engineering	4	2	1	1
Master of Arts	7	1	..	3	3	..
Master of Arts in Science	7	3	1	3
Master of Sanitary Science	36	18	18
Master's Degree (Nurses)	276	22	43	43	32	136
Diploma, Public Health	113	19	20	18	22	34
Diploma, Veterinary Public Health	10	6	4
Baccalaureate Degree (Nurses)	1,785	215	388	361	392	429
Certificate, Public Health	29	4	14	5	2	4
Certificate, Medical Technology	52	..	14	12	14	12
Certificate, Public Health Nursing	2,355	482	443	472	472	486
Other	40	25 ^a	2 ^b	2 ^c	4 ^d	7 ^e

^a Includes 24 certificates in Engineering Science and Management Defense Training and one Master of Science in Engineering

^b Includes two Civil Engineers

^c Includes one each of Doctor of Public Health Nursing and Master of Science in Preventive Medicine and Public Health

^d Includes one each of Master of Science in Hygiene and Diploma of Industrial Hygiene and two Diplomas in Dental Public Health

^e Includes one Doctor of Public Health in Nursing, two each of Master of Science in Hygiene and one each of Sanitary Engineer and Diploma in Industrial Health

latter degree decreased nearly one-fifth and was important in only one school. A further noteworthy development is indicated by the fact that the number receiving Masters degrees in Public Health Nursing was three times as large as in any previous year, while the number receiving the Baccalaureate degree or Certificate in Public Health Nursing increased only slightly (Table 2).

A word about the number of schools offering graduate public health or public health engineering courses. Twenty-

seven schools reported offering such degrees. Of these, 3 had no students registered, 8 had fewer than 5 students, and 14 fewer than 10 students. Thus 669 of the 730 enrolled students were provided for in 10 schools. Of the 416 students receiving degrees in 20 schools, 381 were in 9 schools giving degrees to from 13 to 114 students. The remaining 35 degrees were granted by 11 schools. Among the nursing schools only two granted degrees to fewer than 10 students.

THE CLEVELAND MEETING

THE seventy-fourth Annual Meeting of the American Public Health Association at Cleveland (November 12-14) was one of the most successful in its history. The registration of over thirty-three hundred was the largest recorded for any regular annual meeting held outside New York City. The first General Session was the occasion of an important address by Dr. F. G. Boudreau on the World Health Organization; of the new Lasker awards (discussed in the December issue of this *Journal*); and of the award of the Sedgwick Memorial Medal "For Distinguished Service in Public Health" to Dr. Karl F. Meyer of San Francisco. The highlight of the Banquet was the announcement of the approval of the amended Constitution and of the choice of Professor Harry S. Mustard as President for 1946-1947 and of Dr. Martha M. Eliot as President-elect for 1947-1948. Dr. Mustard's outstanding leadership as an expert in public health administration and as Director of the School of Public Health at Columbia makes him a fitting link in the long chain which carries us back to the days of Stephen Smith; and the selection of Dr. Eliot (the first woman to hold this high office) is an appropriate tribute, not only to a courageous and statesmanlike personality but to the constructive impetus which the U. S. Children's Bureau has given to the cause of public health.

The program of the conference was enriched by a wealth of important technical papers which will be presented in the columns of this *Journal* during succeeding months. Methods for the isolation of the gonococcus, and for the laboratory study of virus diseases, procedures for the disinfection of air, the neutralization of poliomyelitis virus by the serum of patients and contacts, the relation (or lack of relation) between infectious hepatitis and homologous serum jaundice, the importance of the Rh factor, the values of BCG, the sterilization of eating utensils, and the importance of a regional approach in health education were among the specific subjects discussed. Lloyd Florio reported important results on the etiology of Colorado tick fever. Striking data were presented on the effects of acute nutritional deficiency. Many valuable contributions were made in public health engineering, vital statistics, and industrial hygiene. Our youngest Section, dealing with dental health, had an extensive and effective program.

Sessions of the Health Officers Section were particularly stimulating. This group came to grips with such vital administrative problems as the methods of allotting state and federal funds to local units and the program audit, a new device for guiding wisely the expenditure of such funds. Discussion from the floor was active and constructive; and, as at other recent annual meetings, the participation of increasing numbers of keen young health officers was a most heartening phenomenon. W. P. Shepard and R. M. Atwater, however, sounded a note of warning for the future in a paper on "The Key to Better Public Health Service," said key being the establishment of more adequate salary scales in state and local health departments.

The interest of the profession in the newer challenges to the health officer of the future was registered in special sessions devoted to Medical Care, to Housing, and to Problems of an Aging Population. In all these areas we are passing from academic discussions of what ought to be done to scientific analysis of what is being done. In medical service to the indigent, the Maryland State Health Department plan is a going concern; and the symposium on housing brought convincing evidence of the value of the A.P.H.A. procedure for evaluation of sub-standard housing as applied on a large scale in Los Angeles and Milwaukee.

In some ways the most impressive session of all was a Special Session, on the last day, devoted to the actual service projects now being carried forward by the Association itself through its standing committees and staff. Few of our younger members have realized the full extent of such activities. At Cleveland, they learned how the Committee on Eligibility (under Vlado Getting) safeguards the professional standing of the Fellowship of the Association. They heard of the remarkable achievements of the Committee on Administrative Practice (under W. L. Halverson); and, particularly, of the reports of Subcommittees (both led by Haven Emerson) on Local Health Units and on Communicable Diseases. The Health Unit Program is making notable progress throughout the country, seventeen new local full-time health jurisdictions having recently been authorized in one election in the State of Illinois; and the report on the *Control of Communicable Diseases* has been translated throughout the world and formally adopted as standard in many countries. The Committee on Research and Standards (K. F. Maxcy, Chairman), through the Laboratory Section, has completed a new edition of *Standard Methods for the Examination of Water and Sewage* and will shortly have ready a new edition of *Standard Methods for Dairy Products*. Its Subcommittee on the Hygiene of Housing hopes to complete in 1947 a four volume manual on the essential features of sound and healthful housing. The Committee on Professional Education (W. P. Shepard, Chairman) is continuing its invaluable formulations of qualifications for various types of public health personnel, and has established a continuing program of accreditation for schools of public health. The Merit System Unit has had phenomenal success in developing sound procedures for the grading of applicants for various positions in public health, now already in use in half the states of the Union.

In all these activities the staff of the Association, which has been greatly strengthened in recent years, is playing a constructive and ever-increasing part.

All in all, no one could attend the meetings in Cleveland without a growing pride in being a part of an organization which is so fully and effectively fulfilling its responsibilities as the official representative of the profession which has the health of the American people in its charge.

PUBLIC HEALTH AS SEEN BY ENGLISH EYES

ON the way back from Cleveland the editor was interested to look over the proceedings of the Health Congress at Blackpool, held under the auspices of the Royal Sanitary Institute last June. The convention techniques of Great Britain and the United States are widely different. The Cleveland program scheduled over 220 papers and symposia for a period of three days; the Blackpool program, about 35 papers in five days. We encourage a wide range of communications which present the details of new scientific papers and provide a wonderful opportunity for the younger men to try their wings. The British plan presents only a few addresses by outstanding leaders and allows ample leisure for tea and excursions and leisurely social contact. Each type of procedure is an expression of national psychology.

Even more interesting, perhaps, is the difference in fields of interest illustrated by the two conventions. At Cleveland the overwhelming mass of contributions dealt with technical problems in the established fields of laboratory procedure, epidemiology, sanitation, vital statistics, health education, maternal and child health, school health, and industrial hygiene. At Blackpool, only 12 addresses fell within this field, about 37 per cent of all papers presented, as compared with 86 per cent of all papers presented at Cleveland. Problems primarily of interest from the standpoint of public health administration occupied 8 per cent of the American, and 15 per cent of the British program. Nutrition accounted for 5 per cent of the American and 9 per cent of the British papers; hospitalization and medical care for 2 per cent of the American and 6 per cent of the British program; housing and heating and ventilation for half of one per cent of the American and 21 per cent of the British program. The Cleveland convention had 7 papers on dental hygiene, the Blackpool program none; the Blackpool meeting had 3 papers on veterinary medicine, and 1 on traffic control, the Cleveland meeting, none.

Perhaps such an analysis may seem trifling. It certainly will not bear the weight of a statistician's analysis of probable error.

It does, however, suggest two thoughts to the writer. The first of these reactions is a deep pride in the great mass of solid and significant scientific research which is coming from the health services and the universities of North America to form the sure basis for our technical progress in the future. The second question raised is whether we do not need to add to our encouraging process in the basic microbiological, epidemiological, statistical, and engineering foundations of public health a wider vision of its social applications in the future. The organization of the nursery school; the rehabilitation of problem families; aspects of heat, light, and sound in relation to town planning; the care of the aged in health and sickness; roads and traffic problems; housing and slum clearance; and even "Form and Color in Landscape" were among the subjects discussed by our English brethren. It seems probable that our Association in future years may devote a larger proportion of its time to such problems, in regard to which the expert on physiological and psychological health has a vital contribution to make.

THE IMPORTANCE OF CONTROLS IN PUBLIC HEALTH
FIELD STUDIES

NO competent investigator conducts experiments in the laboratory without providing for adequate controls, since the very essence of experimental

research involves the elimination of all but a single variable in the complex chain of biological processes. In statistical research the same end can often be attained by application of the techniques of multiple correlation. In field studies made with regard to the value of an immunization procedure, or the importance of a particular dietary factor, or the influence of an air-conditioning process, the setting-up of effective controls is more difficult and the lack of such controls invalidates many time-consuming studies. The demonstration of the value of influenza vaccine by Army investigators is an example of a study in which proper controls were used.¹ A recent report on the influence of vitamin supplementation on nutritional status of aircraft workers in California² is another excellent example of sound scientific method.

This investigation covered about 500 young male subjects and lasted for about one year. All the volunteers who took part were given a very thorough physical examination—with special emphasis on the delicate modern tests for vitamin deficiency—at the beginning and at the end of the observation period. During this period each subject was given tablets and capsules on five days of each week; but these tablets in the case of one-half the subjects (supplemented group) contained suitable amounts of calcium and of six vitamins; while the other half (placebo control group) received only inert placebos. A third group of workers who received no medication were used as a normal control group. All three groups were closely comparable as regards age, duration of employment, and type of work. No case of severe nutritional deficiency was present in any group but a majority of the subjects had evidence of chronic, mild nutritional deficiency by various special criteria which have been suggested as significant.

Most of the tests thus far advanced for the detection of mild symptoms of dietary deficiency showed no significant difference between the experimental and placebo groups. This was true of abnormalities in reflexes, calf muscle tenderness, plantar dysesthesia, loss of vibratory sensibility to a C-256 tuning fork, thresholds of vibratory sensibility and paresthesias as test of thiamin deficiency; of cheilosis, angular stomatitis, sebaceous plugs, seborrheic dermatitis and corneal vascularization observed with the biomicroscope; and for hematological effects of vitamin mineral deficiency.

Of all the clinical tests employed only three yielded significant differences. Conjunctival opacity as observed with the biomicroscope showed a small but significantly better rating for the experimental group which had received vitamin A; there was a significantly lower prevalence of dryness of hair and a lower prevalence and less extensive follicular hyperkeratosis in the experimental group (due again to higher level of vitamin A); and there was lower incidence of mild degrees of abnormal thickness, abnormal color, and hypertrophied papillae of the tongue (due to supply of vitamin B complex).

The actual incidence of colds was essentially the same for all three groups, although both the experimental and placebo subjects *reported* that they had had fewer colds than in years before, while the normal controls did not. Both experimental and placebo groups reported that their appetites had been improved. In the placebo group, about 70 per cent reported improvement in one or more symptoms which they attributed to the "pills" they had been taking. "It was concluded that this difference in subjective impression between the two experimental groups on the one hand and the control group on the other was a psychotherapeutic effect of participation in the experiment." A larger number of the

placebo than of the vitamin group reported benefits with respect to eye symptoms, weight gain, and miscellaneous conditions. A larger number of the vitamin group reported benefits in colds, appetite, feeling of well-being, less nervousness, less headaches, less constipation, and improved digestion. Only in the case of nervousness was even the difference in subjective opinion statistically significant (7.4 per cent for vitamin group, 1.3 per cent for the placebo group).

These studies should be of material value to the student of nutrition in indicating which tests of nutritional deficiency are really promising. It is clear that with regard to most of the criteria studied, either the tests fail to distinguish between good and bad nutrition or the nutrition of the average warcraft worker in California is adequate. (Some of these tests might, of course, be of value in the study of less well nourished populations.)

The investigation is significant to all of us as a model of the type of thorough and well controlled experiments which can be carried on in many other fields of public health.

CONSTITUTION AND BY-LAWS

As Adopted at the Seventy-Fourth Annual Meeting, November 13, 1946

ARTICLE I NAME

The name of this Association, incorporated under the laws of Massachusetts, is the American Public Health Association.

ARTICLE II OBJECT

The object of this Association is to protect and promote public and personal health.

ARTICLE III MEMBERSHIP

Section 1. There shall be seven classes of constituents to be designated as Fellows, Honorary Fellows, Members, Sustaining Members, Life Members, Affiliated Societies, and Regional Branches.

Section 2. The right to hold office, except the office of Vice-President, or to serve as a member of the Governing Council, the Executive Board, or of a Section Council, or of a standing committee, or as the chairman of a committee of the Association or of a Section, or to vote for elective Councilors or on any amendment to the Constitution shall be limited to Fellows and to Life Members and Honorary Fellows who have been elected Fellows of the Association.

Section 3. The qualifications of the several classes of constituents, and the dues of each of them, the manner of their election, and their rights and privileges, except as specified in this Constitution, shall be established in the By-Laws.

ARTICLE IV GOVERNING COUNCIL COMPOSITION

Section 1. There shall be a Governing Council which shall consist of:

(a) The officers of the Association and the elective members of the Executive Board.

(b) The Chairman, Vice-Chairman, and Secretary of each Section, and the elective members of the Council of the Health Officers Section.

(c) One representative to be designated by each Affiliated Society.

(d) One representative to be designated by each Regional Branch.

(e) Thirty members of the Council, to be elected by the Fellowship of the Association, for three-year terms, one-third of whose terms shall expire each year. Such members of the Council shall be known as elective Councilors and shall be nominated and elected as provided for in the By-Laws. If an elective

Councilor is elected a Section Chairman, Vice-Chairman, or Secretary, or an elective member of the Council of the Health Officers Section, or appointed the representative of an Affiliated Society, or of a Regional Branch, a Councilor to fill such vacancy shall be elected by the Governing Council. All vacancies while in office shall be filled by election for the unexpired term. After two consecutive terms, an elective Councilor shall be ineligible for reelection to the Council during one Association year.

Section 2. The terms of all Councilors, except the representatives of Affiliated Societies and Regional Branches, shall begin at the end of the annual meeting at which they are elected, and shall terminate at the end of the annual meeting at which their respective terms expire; provided that newly elected Councilors shall have the right to attend meetings of the Council in an advisory capacity as soon as elected.

The terms of the representatives of Affiliated Societies and Regional Branches shall begin and terminate in accordance with the constitutions and by-laws of their respective organizations.

Section 3. The Officers of the Association shall be the Officers of the Council.

Section 4. A Quorum of the Council shall consist of twenty Councilors.

Section 5. Meetings of the Council shall be called by the Executive Secretary at the request of the President, or at the request in writing of any twelve Councilors. In the latter case, the call to the meeting shall be issued at least twenty days in advance of the meeting and shall state the purpose for which it is called.

ARTICLE V GOVERNING COUNCIL FUNCTIONS

The functions of the Governing Council shall be:

Section 1. To establish and amend the By-Laws of the Association.

Section 2. To establish policies for the Association and for the guidance of the Executive Board and the Officers.

Section 3. To consider all resolutions proposed for approval in the name of the Association, and to receive and act upon a report from a committee on resolutions appointed annually by the President.

Section 4. To approve all standards

promulgated in the name of the Association.

Section 5. To receive at its first session at the time and place of the annual meeting of the Association, a report from the Chairman of the Executive Board in which the work, the accomplishments, and the financial status of the Association during the year preceding such annual meeting shall be reviewed and a statement made of the major activities contemplated for the ensuing year.

Section 6. To establish Sections of the Association; to combine or discontinue them when necessary; to prescribe the qualifications of the members of Section Councils and the chairmen of section committees; to maintain coördination among Sections; and to formulate general rules governing their policies.

Section 7. To elect the Executive Board, the officers of the Association, with the exception of the Chairman of the Executive Board and the Executive Secretary, to elect Fellows, Honorary Fellows, Life Members, and Affiliated Societies, and to establish Regional Branches.

Section 8. To publish after each of its meetings an abstract of the minutes of such meeting.

ARTICLE VI OFFICERS

The officers of this Association shall be a President, a President-elect, three Vice-Presidents, an Executive Secretary, a Treasurer, and the Chairman of the Executive Board. The officers, with the exception of the Chairman of the Executive Board and the Executive Secretary, shall be elected by written ballot of the Governing Council as provided in this article and in the By-laws. The President-elect shall serve as such from the close of the annual meeting at which he was elected to the close of the next annual meeting, when he shall automatically become President. As President he shall serve to the close of the next succeeding annual meeting. However, in case of the inability of the President to complete his term for any reason, the President-elect shall at once succeed to the duties of President, filling the unexpired term of his predecessor and his own term consecutively. Other officers, except the Chairman of the Executive Board and the Executive Secretary, shall serve from the close of the annual meeting when elected until the close of the next annual meeting, and all officers shall serve in any case until their successors are elected and qualified. A majority vote of the Councilors voting shall be required to elect, and if no candidate receives a majority vote on the first ballot, the candidate receiving the smallest number of votes shall be dropped after each ballot in succession until a majority vote is obtained.

The Chairman of the Executive Board and the Executive Secretary shall be elected by the Executive Board, which Board shall define the duties and authority of these officers, respectively.

ARTICLE VII EXECUTIVE BOARD

Section 1. There shall be an Executive Board, consisting of the President, the President-elect, the Treasurer, and six members, to be known as the Elective Members, elected for terms of three years each by the Governing Council. The Elective Members shall be at the time of their election past or present members of the Governing Council. The terms of the Elective Members shall begin at the close of the annual meeting at which they are elected and terminate at the end of the annual meeting at the expiration of their respective terms. The terms of two Elective Members shall expire each year in rotation.

Section 2. Acceptance of membership on the Executive Board shall terminate any appointment such Fellow may hold on any of the standing committees of the Association.

Section 3. It shall be the duty of the Executive Board to direct the administrative work of the Association; to act as the Trustee of the Association's properties; to elect the Members and Sustaining Members; and in general to carry out the policies of the Governing Council between meetings of the latter.

It may designate an Assistant Treasurer whose powers shall be limited to the disbursement of funds in accordance with duly authorized budgets for the ordinary conduct of Association business. Such power shall be exercised only during a period when, in the opinion of the Board, an emergency is created due to the absence or disability of the Treasurer. Such Assistant Treasurer may be a Fellow or a corporate fiduciary institution.

In the event of a vacancy in the office of Treasurer, the Executive Board shall have power to elect a Fellow to serve as Treasurer for the unexpired term.

It shall have such further powers and duties as may be prescribed in the By-Laws.

Section 4. A Quorum of the Executive Board shall consist of five members.

ARTICLE VIII AMENDMENTS

This Constitution may be amended by a two-thirds vote of the Fellows of the Association present and voting at an annual meeting, provided that the specific amendment to be acted upon is published in the official publication of the Association not less than thirty days prior to the meeting, and provided further that the amendment receives the approval of the Governing Council.

BY-LAWS

ARTICLE I FELLOWS

Section 1. Professional health workers who have been members of the Association for at least two years, and who are of established professional standing in the field of public health (whether employed by public or private organizations or in independent private practice) shall be eligible for election as Fellows, provided that the applicant shall have reached his thirtieth birthday at the time application for Fellowship is made and subject to the further conditions of this Article.

Section 2. The following persons shall be considered to have an established professional standing in public health for this purpose:

(a) A person who has rendered acceptable service for two or more years in a responsible public health position and who has been awarded in course a degree of Doctor of Public Health, Doctor of Science in Public Health, Doctor of Philosophy in Public Health, Doctor of Medicine with at least one year of graduate study in public health in a university, Master of Public Health, Diploma in Public Health or other equivalent degrees, according to standards approved by the Executive Board of the American Public Health Association.

(b) A person who has been awarded in course an academic or professional degree involving training in public health and who has been regularly engaged in health work for at least five years, having rendered meritorious service as a health officer or in responsible charge of work in either a public or private health agency.

(c) A person who has done notable original work in public health or preventive medicine of a character to give him a recognized standing.

(d) A person regularly engaged in health work for at least five years, who has given evidence of special proficiency, who has attained a recognized standing.

(e) A teacher of public health or one of its constituent sciences who has attained distinction as an expounder of the principles of public health or its constituent sciences. Such a teacher shall have had at least five years' experience as a teacher of public health subjects. Any years of experience as defined in paragraphs (b) and (d) that the applicant may have had shall be considered the equivalent

of the same number of years' experience as a "teacher."

(f) A person not covered by the above, who has made substantial contributions to public health work in his chosen branch and who has attained a recognized professional standing.

Section 3. Every application for Fellowship shall be made on an approved form and shall be sponsored by two Fellows of the Association who shall be Fellows of the Section with which affiliation is desired, provided, however, that when affiliation with a Section is not desired, the sponsors may be any two Fellows in good standing in the Association. Fellows without Section affiliation shall be known as unaffiliated Fellows.

Section 4.

(a) When an application has been duly sponsored and otherwise completed, it shall be transmitted to the Administrative Office of the Association, which shall make note thereon of such knowledge as it may have concerning the standing of the applicant in the Association. The application shall be forwarded by the Administrative Office to the Secretary of the Section in which affiliation is desired for the action of the Section Council, and, when acted upon by the Section Council, he shall return it to the Administrative Office after he shall have endorsed thereon the action of the Section Council. When the application is for unaffiliated Fellowship, the Executive Board of the Association shall act in place of the Section Council. To be eligible for election, individuals applying for Fellowship under the provisions of subsections (a) and (b) of Section 2 of this Article shall require for approval a majority vote of the Section Council or the Executive Board. All other applicants shall require for approval a two-thirds vote of such Section Council or the Executive Board.

(b) When the application has been approved by the Section Council or the Executive Board, as above provided, it shall be voted upon by the Committee on Eligibility. Applications requiring a majority vote of the Section Council or Executive Board shall require for approval a majority vote of the Committee on Eligibility. All other applications shall require unanimous approval of the Committee on Eligibility. If approved, as above specified, and provided the name of

the applicant shall have been officially published at least fifteen days in advance, the application shall be voted upon by the Governing Council, and if approved by three-fourths of the vote cast, the applicant shall be declared elected a Fellow.

Section 5.

(a) A Fellow may belong to and vote in only one Section, but such affiliation may be transferred to another Section if approved by vote of a majority of the Council of the latter Section. Unaffiliated Fellows may become affiliated with a Section if approved by vote of a majority of the Council of the Section with which affiliation is desired.

(b) Fellows shall have all the rights and privileges provided for Members in addition to those specifically reserved to them by the Constitution and By-Laws.

Section 6. Honorary Fellows may be elected by a three-fourths vote of the Governing Council for distinguished service in public health. Honorary Fellowship shall not confer voting power but Honorary Fellows who have previously been Fellows of the Association shall retain all the privileges of Fellowship.

ARTICLE II MEMBERS

Section 1. Persons professionally engaged or interested in public health work shall be eligible for election as members by a three-fourths vote cast by the Executive Board when sponsored by two members or Fellows and after approval by the Committee on Eligibility. They shall be entitled to receive the official journal of the Association, to vote for the officers and members of the Council of the Section with which they are affiliated, and upon all motions and resolutions coming before such Section, to participate generally in its proceedings and to serve on committees, except as provided in the Constitution and By-Laws. A member may belong to and vote in only one Section, but such affiliation may be transferred to another Section if approved by vote of a majority of the Council of the Section to which change is desired. Unaffiliated members may become affiliated with a Section if approved by vote of a majority of the Council of the Section with which affiliation is desired.

Section 2. Individuals or corporations interested in public health may be elected to Sustaining Membership by a three-fourths vote of the Executive Board. Sustaining Members shall be entitled to receive the journal and such other publications of the Association as the Executive Board may designate.

Section 3. Upon the recommendation of the Committee on Eligibility, any individual member or Fellow of the Association may be elected a member for life. The dues for Life Members shall be \$100.00, payable within one year after election. Election to this grade shall not affect the privileges held by such an individual as a regularly elected Member or Fellow.

ARTICLE III AFFILIATED SOCIETIES

Section 1. A state or provincial public health association or similar regional society including more or less than a state, primarily composed of professional public health workers and organized for the same general objects as the American Public Health Association, may be elected by a three-fourths vote of the Governing Council as an Affiliated Society, provided that not less than twenty of its active members and at least one-half of its active members are members or Fellows of the American Public Health Association. Not more than one such society shall be admitted from the same area.

Section 2. A society applying for affiliation shall submit a copy of its constitution and by-laws, its last annual budget, a roster of its members, and such other evidences of its qualifications as may be required. It shall submit annually and at other times such reports on its financial standing, membership, and other matters as may be required by the Executive Board of the American Public Health Association.

Section 3. The Committee on Eligibility shall consider all applications for affiliation and report its recommendations to the Governing Council.

ARTICLE IV DUES

Section 1. Honorary Fellows and Life Members shall be exempt from the payment of annual dues. The dues of all other constituents are payable annually in advance.

Section 2. The dues for Members shall be \$5.00, for Fellows \$10.00, and for Sustaining Members \$100.00 or more.

Section 3. The dues for Affiliated Societies shall be one per cent of their gross annual income, provided that the minimum dues per society shall be \$10.00 per year, and provided further that for every Fellow or Member paying annual dues to the American Public Health Association, the Association shall remit to the Affiliated Society of which such person is a member the sum of \$1.00 per annum.

ARTICLE V DISCONTINUANCE OF MEMBERSHIP

Section 1. Constituents of any class whose

dues are unpaid for six months or more shall be considered not in good standing. Constituents not in good standing shall not be entitled to any of the privileges or powers of membership, Fellowship, or affiliation. Good standing may be resumed upon the payment of all arrears and dues in advance for one year, provided the lapsed period is not greater than one year. The Administrative Office shall notify by registered mail all constituents who have been in arrears for a period of eleven months. The names of constituents in any class whose dues remain unpaid for one year or more and who have been duly notified as above provided shall be presented to the Executive Board which shall order the names of such constituents stricken from the membership roll. Constituents whose names have been stricken from the rolls in this manner may be again admitted in the manner provided for the election of new constituents in the class for which they make application, provided such person or organization complies with the eligibility requirements at the time the new application is made.

Section 2. If, in the opinion of the Executive Board, any member or Fellow of the Association permits the use of his name, or otherwise allows himself to be quoted or used for illustration in the advertising of a commercial product, in such a manner as to reflect discredit upon the Association, his Fellowship or membership in the Association shall thereupon be terminated.

Section 3. Upon the recommendation of the Committee on Eligibility the Governing Council may discontinue the membership, Fellowship or affiliation of any constituent. Three-fourths of the votes cast shall be necessary for such action.

ARTICLE VI PUBLICATIONS

Section 1. All publications of the Association and of its Sections shall be issued under the direction of the Executive Board.

Section 2. *The American Journal of Public Health* shall be the official journal of the Association. The Executive Board shall appoint a Managing Editor of the official journal and an Editorial Board of not less than five members to serve at the pleasure of the Executive Board. All papers and reports for the annual meetings are to be accepted with the understanding that they shall be the property of the Association for publication, unless this right is waived by the Managing Editor.

ARTICLE VII ELECTIVE COUNCILORS

Section 1. The Elective Members of the

Governing Council shall be nominated and elected as follows:

There shall be a Nominating Committee composed of one Fellow elected by each Section at the preceding annual meeting, and an additional Fellow designated by the Executive Board, the latter serving as Chairman.

This committee shall present to the Administrative Office at least two months before the next annual meeting the names of at least twenty and not more than thirty Fellows of the Association selected with due regard to geographical and membership considerations as nominees for the Governing Council.

Upon the petition of twenty-five Fellows the Nominating Committee shall add the name of any Fellow to the nominees selected by it, provided such petition is received not less than fifteen days before the annual meeting.

Section 2. The Administrative Office shall publish to the membership not less than thirty days prior to the annual meeting the nominees selected by the Nominating Committee. Prior to the annual meeting it shall prepare ballots upon which the names of all nominees shall appear in order determined by lot and one such ballot shall be handed to each Fellow entitled to vote at the annual meeting upon his signing a receipt therefor.

Section 3. The polls for the reception of ballots shall be open at 9 A.M. on the first day of the annual meeting and shall close at a time to be determined each year by the Executive Board prior to the opening of the polls.

Section 4. The Fellows receiving the highest number of votes on a written ballot cast by the Fellows present and voting at the annual meeting shall be declared elected to fill existing vacancies. Should two or more candidates receive the same number of votes, the Governing Council shall, when necessary, determine by written ballot the order of precedence of such candidates.

ARTICLE VIII EXECUTIVE BOARD

Section 1. The Executive Board shall elect from its own membership a Chairman who shall serve in that capacity for such term as the Executive Board shall determine. It shall also designate such other officers of the Board as it may require for the conduct of its business.

Section 2. If a vacancy among the Elective Members of the Executive Board shall occur after the annual meeting, the President shall designate a nominating committee from the Governing Council. Such committee shall

nominate not less than three candidates for the vacancy, from among whom the candidate receiving the highest number of votes of the Governing Council in a mail ballot shall be declared elected to the Executive Board to fill the vacancy.

Section 3. In addition to those prescribed in the Constitution and in these By-Laws, the Executive Board shall have the following powers and duties:

(a) To plan methods for the procurement of funds.

(b) To approve the budgets for the Association's work.

(c) To conform to the policies of the Governing Council in the conduct of its work.

(d) To designate the chairmen of the standing committees, to appoint their members unless otherwise provided in these By-Laws. To authorize the establishment of all other Association committees and confirm the appointment of their members.

(e) To transmit a report of its proceedings and transactions to the Governing Council at least thirty days before each annual meeting.

Section 4. After two consecutive terms of three years an elective member of the Executive Board, except one serving as chairman, shall be ineligible for reelection during one Association year.

ARTICLE IX NOMINATION OF OFFICERS

The officers elected by the Governing Council shall be nominated from the floor by that body.

ARTICLE X STANDING AND SPECIAL COMMITTEES

Section 1. There shall be four standing committees of the Association as follows:

(a) Committee on Eligibility.

(b) Committee on Administrative Practice.

(c) Committee on Research and Standards.

(d) Committee on Professional Education.

Section 2. Each standing committee shall designate from among its membership such officers as it may require for the conduct of its business and shall control its policies within the limitations prescribed by the Governing Council and the Executive Board. The Executive Secretary shall be a member, ex-officio, and serve as secretary of each standing committee.

Section 3.

(a) The Committee on Eligibility shall consist of one Fellow to be elected by each Section and an additional Fellow elected by the Executive Board who shall serve as

Chairman. Members shall serve for a term of two years.

(b) This committee shall pass upon the eligibility of Fellows, members and other constituents in accordance with the provisions of the By-Laws.

Section 4.

(a) The Committee on Administrative Practice shall consist of fifteen Fellows, twelve of whom shall be designated by the Executive Board to serve for a term of four years, the terms of three members expiring each year, and three of whom shall be elected annually by and from the Fellows affiliated with the Health Officers Section.

(b) This committee shall engage in the collection of information regarding current public health practices and analyze the material obtained to derive standards of organization and achievement. The findings and standards may be made available to public health workers through publications, information and field service under such conditions as the committee may establish. No standards shall be promulgated as the official and authorized judgment of the Association except with the approval of the Governing Council.

Section 5.

(a) The Committee on Research and Standards shall consist of fifteen Fellows representative of the various Sections of the Association appointed by the Executive Board. Members shall serve for a term of three years, the terms of five members expiring each year.

(b) This committee shall be responsible for carrying out research and the development of standards in the technical branches of public health service, and shall coordinate such research and standardization. This committee shall also be charged with the duty of reviewing from time to time standards already established. No standards shall be promulgated as the official and authorized judgment of the Association except with the approval of the Governing Council.

Section 6.

(a) The Committee on Professional Education shall consist of twelve Fellows appointed by the Executive Board. Members shall serve for a term of three years, the terms of four members expiring each year.

(b) This committee shall be responsible for carrying out research and the development of standards for professional education and training in public health work and shall perform such other functions as may be delegated to the committee by the Governing Council with the view of maintaining professional qualifications of high standard. No standards shall be promulgated as the official

and authorized judgment of the Association except with the approval of the Governing Council.

Section 7. Unless otherwise provided in these By-Laws, all other Association Committees shall be authorized and appointed by the Executive Board and the appointments of their members shall expire at the next annual meeting.

ARTICLE XI SECTIONS

Section 1. The Executive Board shall approve rules and regulations relating to the government of the Sections, and to the appointment of administrative committees. Each Section shall elect its own officers and shall name its respective Section committees. The right to hold office or to serve as a member of a Section Council or as chairman of a committee in a Section shall be limited to the Fellows affiliated with such Section.

Section 2.

(a) The Section Chairman, with the advice of the Section Council, shall appoint a Committee on Nominations from the Fellows affiliated with the Section at least fifteen days before each annual meeting. The Section Secretary shall be a member of such committee.

(b) The names of the members of the Committee on Nominations shall be announced at the first meeting of the Section at each annual meeting of the Association. The Committee on Nominations shall present at the second meeting of the Section a list of nominees for the Section officers, and for membership in the Section Council; provided that if the name of any Fellow be transmitted to the Nominating Committee over the signature of ten Fellows of the Section prior to the second meeting of the Section, the Nominating Committee shall add the name of such Fellow to its own list of nominees.

Section 3. The officers of each Section shall be a Chairman, a Vice-Chairman, and a Secretary, who shall be the representatives of the Section to the Governing Council of the Association, except as provided in the Constitution.

Section 4. New terms shall begin and old terms shall expire at the end of annual meetings. After five consecutive years in any elective Section office, except that of Secretary, a member shall be ineligible to reelection to that office during one Association year.

Section 5. The Chairman, or in his absence the Vice-Chairman, shall preside at meetings of the Section.

Section 6. The Secretary shall prepare the scientific program of the Section for the annual meeting, subject to the recommendations

of the Section Council, and shall submit same to the Administrative Office. He shall keep the minutes and other records of the Section, and shall transmit to the Executive Secretary of the Association a copy of the minutes of both the business and scientific sessions as soon as practicable after the close of the annual meeting of the Association. When unable to be present at meetings, he shall thoroughly instruct a substitute as far in advance of the meeting as possible.

Section 7. There shall be a Section Council composed of the three officers of the Section and five members, to be known as the elective members, each of whom shall be elected for a term of five years; provided that when a Section is first established one member shall be elected to serve for one year, one for two, one for three, one for four, and one for five years.

Section 8. The duties of the Section Council shall be:

(a) To recommend papers, and to make general recommendations in relation to the annual meeting program.

(b) To advise on Section membership and on Section policies.

(c) To submit annually to the Governing Council through the Executive Board a report of the transactions of the Section.

(d) To report annually to the Governing Council through the Executive Board on the plans, scope and policy of the Section during the succeeding year.

(e) To formulate rules of procedure for the Section.

(f) To consider and transmit to the Governing Council resolutions originating in the Section. Only resolutions approved by the Governing Council shall be published as representing the policy of the Association.

(g) To advise on the publication of papers and reports presented at the Section meetings.

(h) To advise with respect to the appointment of technical committees, subcommittees, or Section representatives on committees of the Association.

ARTICLE XII FINANCES

All remittances to the Association shall be deposited to the account of the Treasurer. The Treasurer shall be custodian of investments of the Association and shall disburse funds in accordance with duly authorized vouchers. With the approval of the Executive Board he may establish a drawing account for the Executive Secretary, who shall send to members of the Executive Board a financial summary of receipts and disbursements each month. Once each month, or oftener if called

for, he shall also forward to the Treasurer and to the Chairman of the Executive Board an itemized statement of all expenditures. The Executive Secretary, the Treasurer and the Assistant Treasurer shall be bonded at the expense of the Association in an amount to be determined by the Executive Board. The books of the Association shall be audited annually by certified public accountants to be appointed by the Executive Board.

ARTICLE XIII MEETINGS OF THE ASSOCIATION

There shall be one general meeting of the Association, to be known as the annual meeting which shall be held each year at a place selected by the Governing Council. Special

meetings of the Association may be called by a majority vote of the Governing Council, the Executive Board, or the Association. In all proceedings of the Association, *Robert's Rules of Order* shall be official.

ARTICLE XIV AMENDMENTS

These By-laws may be amended by a two-thirds vote of those voting on the Governing Council during the annual meeting, provided that twenty-four hours prior written notice thereof has been given. The By-laws may further be amended by a two-thirds vote of those voting at any meeting of the Governing Council called for the purpose, provided that notice thereof shall have been given at least fifteen days prior to such meeting.

Public Health Work in England: How It Is Like and Unlike Ours.

London letter by the Roving Editor of the American Journal of Public Health

MARGARET G. ARNSTEIN, R.N., M.P.H., F.A.P.H.A.

THIS is a particularly interesting time to be in England observing health work, for the new National Health Service Bill is being debated now in Parliament and consequently the health work of the nation is discussed frequently and prominently in the newspapers and is at the forefront of everyone's mind. However, the very fact that one is present during a period when great changes in the present system are imminent makes it more difficult to give any report which will not be out of date by the time it is printed.

Nothing less than a full length book would suffice to describe all the things which seem to this observer to be of special interest to American health workers, to say nothing of any consecutive account of the scope and content of health work in the British Isles.

It has been difficult to choose from the things heard and seen those which can fit together into the confines of a letter from England. However, a few of the problems and achievements which strike one's attention because of their amazing similarity to ours, and in a few which stand out as differing quite sharply from our practices, are presented here.

A MULTIPLICITY OF HEALTH AGENCIES OPERATE IN A COMPLEX GOVERN- MENTAL STRUCTURE

Health departments in England provide not only all the services habitually performed by our health departments, but also housing, and many functions

which are usually carried out by our welfare departments, such as the administration of public hospitals, children's institutions and foster homes.

In England as in the United States there are numerous agencies carrying on various health functions in an equally complicated governmental framework. In a county the tuberculosis and venereal disease work may be administered by the County Health Authority (County Health Department) for the whole county. This same body may administer the maternity, infancy, and preschool work in certain parts of the county, while a dozen or more municipal boroughs (cities) and urban districts (villages) within the county administer their own communicable disease programs and perhaps also their own maternity—infancy programs. Certain cities, called County Boroughs, are entirely independent of the County Health Authority and administer all health services within the city.

The school health work¹ is administered by the education authorities, though coördination of work is achieved in Great Britain by the Medical Officer of Health also being the School Medical Officer. There are also many voluntary agencies operating alongside the official. There are district nursing associations in almost every county in England, and in all but 10 of the 61 administrative counties in England and Wales these associations are affiliated with the Queen's Institute of District Nursing. Such organizations as the National

Association for the Prevention of Tuberculosis and the Crippled Guild may hold clinics and even run hospitals in certain areas; the British Empire Cancer Campaign provides facilities for diagnosis and treatment in association with voluntary hospitals, and the British Red Cross carries on a multiplicity of peacetime activities, to mention but a few of these voluntary agencies.

As an example of the complexity of organization, in one large quite typical county visited, the County Health Authority employs 36 health visitors and 53 midwives. The health visitors do the tuberculosis work for the entire county, the maternity and infancy work in part of the county, and the school nursing in the entire county with the exception of 6 areas where the Education Authority employs 6 full-time school nurses. The midwives cover the whole county, many parts of which are also served by the District Nursing Association nurse-midwives. Seventy-seven district nurses in this county are employed by 61 separate associations affiliated with the County Nursing Federation which, in turn, is part of the Queen's Institute of District Nursing. The County Nursing Superintendent (nursing supervisor) supervises the nurses in these associations and coordinates their work. There are another nine district associations in the county which are not affiliated with the County Federation but which work independently.

The above presents a picture in only one branch of the health service, other branches such as clinic and hospital services being almost as complicated, voluntary agencies offering services in certain places and not others, hospitals serving parts of the county, or taking certain types of cases from other counties.

This type of organization with its multiplicity of agencies and overlapping of services is an all too familiar pattern

to us in the States and is deplored in Britain as much as it is at home. However, there is a definite prospect that the situation will at least be partially remedied by the National Health Service Bill which unifies the official services under the major local authorities, counties and county boroughs (cities), so that when the Bill is passed minor local authorities (small cities and villages) will transfer whatever health activities they are now conducting to the County Health Authority.

REGIONALIZATION OF HOSPITALS

The National Health Services-Bill will also break down boundaries in relation to hospitals, which are to be grouped into regions and administered by Regional Boards, not by local health authorities or voluntary boards, as they are now. The regions are planned around the existing medical teaching centers. Hospitals within the region will serve their "natural" areas, not necessarily a governmental unit, population grouping and transportation facilities being the factors defining an area rather than boundaries of cities or counties. Voluntary hospitals will be included in this scheme, for they are to be taken over by the government.

This scheme for the regionalization of hospital services resembles closely the plans which many public health workers in the United States have been making, writing about, and hoping to see in operation. At this moment a similar plan is being tried out in and about Rochester, N. Y., with the assistance of private funds, and the Hospital Construction Act passed by Congress enables the U. S. Public Health Service to promote and assist with the development of similar plans in the various states. It is therefore intensely interesting to see another country in the throes of putting these ideas into practice, getting down to practical details of administration, such as the employment

and assignment of personnel. (Though the National Health Bill has not been passed yet as this is written, there seems no doubt that it will pass in substantially its present form.)

GENERALIZATION VERSUS SPECIALIZATION IN PUBLIC HEALTH NURSING

Another familiar problem under discussion here is the extent to which public health nursing activities should be generalized. It seems "just like home" to find that in some areas there are three groups of nurses, health visitors (Board of Health nurses), school nurses and district nurses, while in others the health visitor does the school nursing and board of health work, and in the most rural areas one nurse does the work of all three groups, including midwifery.

The planning and operation of a generalized public health nursing service which includes midwifery is more difficult than one which does not offer this service, as those in the United States who have included delivery nursing service in their program know. However, it seems to offer fewer difficulties here, at least in the rural areas, than at home. The nurse midwives are left to plan their own time off and to arrange with a neighboring nurse to take their calls if they wish to go away for an afternoon or evening, but a relief nurse is supplied from county headquarters for more extended periods off duty. The midwife like the physician is always "on duty" and must always leave word where she can be reached. Many American public health nurses would feel tied by this system and would want a regular schedule of time off duty. As far as one can tell by contact with only a few district nurse midwives, they seem to be content. Their independence plus the interests and responsibilities of midwifery seem to compensate for so little time off call. The number of hours actually on duty is very variable, of

course, but in the county visited was seldom more than 40-44 hours a week. However it must be noted that there is an extreme shortage of midwives and it is thought that the hours of work may be one of the factors discouraging nurses from practising midwifery, though it is certainly not the only factor.

The trend here, as at home, is toward more generalization, and the same questions arise as to how far one can carry this policy and in which places it is practical.

VOLUNTARY AGENCIES AND HEALTH EDUCATION

The Central Council for Health Education, which was established to co-ordinate the health education activities of some fifty national health agencies, is of particular interest to us at the present moment while the Gunn-Platt report is being discussed and acted upon in communities all over the United States. This Council does not attempt to coördinate the total program of the various agencies but it does act as a clearing house for their health education activities, and produces materials for all of them. The Council is supported by a grant from the Ministry of Health and grants from the local authorities and thus is also an official agency doing a large part of the health education work for the Ministry of Health. The Council prepares and distributes literature on all phases of health and, in spite of paper shortage and printing difficulties, many of these pamphlets are so readable, attractive and eye-catching that one wishes JOURNAL readers could see them, not merely hear about them. Movies, radio programs and lecture material are also prepared and distributed locally.

In addition to the central office in London there are 13 regional offices. The staff members in these regional offices work directly with local medical officers of health, advising and assisting

them in planning special campaigns. They not only draw up a budget for the campaigns and indicate sources of material, or voluntary organizations equipped to assist them, but they may also work with local groups in organizing the work. We have found this type of assistance from trained health educators of tremendous value in the few places where it has been tried on a more or less experimental basis. England is already carrying out this scheme on a national basis, though shortage of trained personnel has to date limited the amount of assistance given to local health authorities.

What the future of the voluntary agencies will be no one knows. As has been stated, the new National Health Bill provides for the government taking over all voluntary hospitals and, though it is not quite clear yet what will happen to the largest operating voluntary organization, the Queen's Institute of District Nursing, it seems fairly certain that there will be important changes in the financing of this agency as well. It is too soon for anyone to say how the Act will affect other voluntary agencies.

MINISTRY OF HEALTH CAMPAIGN FOR DIPHTHERIA IMMUNIZATION

The Ministry of Health has a public relations division of its own which carries on certain phases of the health education program not covered by the Central Council for Health Education. It gives material to the women's magazines regularly and frequently and to the newspapers, though the extreme shortage of newsprint has limited newspaper publicity. The Ministry of Health also has certain moving pictures made, does some radio broadcasting, and carries on national campaigns, such as that against diphtheria.

Americans are rather apt to think of the English as slow moving or at least not "pushers." The success of the

diphtheria immunization campaign is an example of the danger of all such generalizations. In four years the immunization status in the whole country was raised for children under 16 from 5 to 58 per cent and for those under 5 from almost zero to 50 per cent.

This was done through intensive campaigns of education and persuasion, not regulation, much as we did when we started to promote diphtheria immunization some years ago. England, perhaps partly because it is smaller and more homogenous, has achieved a greater uniformity of success over the whole country in four years than we have in fifteen years. Much the same methods have been used: education of the public through posters prominently and widely displayed in all public places and through radio programs, literature, and talks, and, most effective here, as at home, the visits of the public health nurse. Great Britain is as free from centralized dictatorship rule as we are, so this campaign had to be carried out by fifteen hundred separate local health authorities. A survey made for the Ministry of Health in October, 1945, showed a remarkably high performance from almost all the local authorities. This survey found that very few people (only 1 per cent of mothers whose children had been immunized) reported any difficulty in getting the immunization done, an indication that the local authorities had made facilities easily available and had publicized them well.

These are a few of the features which seem very similar to our problems and achievements. There are many others in this category, such as the difficulty in obtaining sufficient nurses for public health work or hospitals, the equal difficulty of obtaining domestic staff for hospitals, the acute shortage of personnel in tuberculosis and mental hospitals, all of which are in the forefront of everyone's thoughts.

WHY SOME HEALTH PRACTICES DIFFER FROM OURS

There are also many strikingly different practices and viewpoints, some of which appear to be due to the differences in geography and size of the two countries.

For instance, it has been possible entirely to eliminate rabies by quarantine regulations at the ports, an achievement which would be almost impossible in a country like the United States. Similarly, though only about 30 per cent of the children born each year are vaccinated against smallpox, there has been no widespread outbreak for some years. Smallpox vaccination has been compulsory, but a waiver allowing exemption was so easy to obtain that less than one-third actually were vaccinated. The new National Health Bill removes the compulsory vaccination feature because the regulation as it now stands is a farce. In view of the great success of the diphtheria immunization campaign one might expect health officials to be preparing similar campaigns for voluntary vaccination, but such apparently is not the case at the present time. In spite of the fact that airplanes have reduced the importance of seaports as quarantine stations and disease barriers, there is still a strong feeling among the local health officials met in the course of these observations that smallpox, if introduced, could easily be controlled. They feel that the risk is relatively small and, in view of the strong public prejudice against vaccination, it would not be worth the time and expense to try to overcome it at the present time.

Many more of the differences in health practices are due to the differences in our two social structures and the degree to which not only medicine but other phases of life have been socialized here and are being rapidly brought more and more under governmental control. This is such an important and fundamental difference,

influencing every health activity no matter how minute, that great readjustments in thinking are needed if the American visitor is not to make mistakes in analyzing the health work in England.

Another fact which must also be kept constantly in mind is that most of the obstetrics is done by midwives, which influences not only the care of the patient, but also such related practices as personnel policies for district nurses, and the number of physicians needed in an area.

FOOD DISTRIBUTION IN ANTEPARTUM AND INFANT CLINICS

Post-war shortages, rationing of food and clothing, and the difficulties of shopping also play an important part in determining certain policies and practices. For instance, to an American public health worker it is surprising to see orange juice, prepared dried milk formula powders, vitamin preparations, and certain other foods sold or given free at all well run baby and prenatal clinics. This is done to simplify the mother's life a little, as it cuts out some tedious visits to the food office. Even a short period of housekeeping in England makes one appreciate any procedure which reduces the number of places one has to go and the number of times one had to stand in line. One argument we use at home against giving food at clinics does not apply here, others do not fit into their social philosophy. We say one should not mix "relief" with health work, but this is not relief in our sense, for all pregnant women, regardless of financial status, are entitled to these foods at the reduced clinic prices, and one item, orange juice, can only be obtained at the clinic or the food office. The shortage of many protective foods has made supplementary vitamins essential and, though they are obtainable in the shops, they cost much less at clinics. The aim in Great Britain is to make sure that no mother

or baby should be deprived of necessary foods for lack of funds, and it is not thought advisable to depend only on educating the mother to plan her budget so that she can buy these items on the open market. In the United States we think that we should educate mothers to attend clinics for the medical and nursing supervision they receive and that they should not come in order to get "hand outs." The English public health workers think that, as long as they come to the clinic and remain under supervision, the reason for their attendance is unimportant.

Whether one thinks distributing food at clinics is good or bad, one must come to a conclusion only after careful study of the whole situation in England, and probably it takes longer than a few months to understand all the implications and consequences of this policy.

Another factor which has a bearing on the situation is the high percentage of women who attend prenatal clinics. Seventy-six per cent of the mothers of all babies born in 1944 attended prenatal clinics! This is an amazing figure, probably not equaled anywhere in the United States. Though some may come and come early in order to get a physician's certificate, without which they cannot get their extra food and clothing coupons—others in order to reserve a hospital bed—this is probably not a very large factor, for in 1938 sixty-one per cent of all prenatals attended clinics and this number was then on the increase.

The large number of prenatals attending clinic has resulted in very overcrowded clinics. Examinations and interviews are necessarily brief and little teaching can be done in clinic. The shortage of medical and nursing personnel has made it impossible up to date to increase the number of clinic sessions, but in each area visited, plans have been made to remedy this situation as soon as more personnel are available.

MATERNITY CARE—POSTPARTUM PERIOD

Though 76 per cent of the prenatals attended clinic during the antenatal period, only a very small percentage attended postnatal clinics. The postnatal clinic service has received attention only recently and is now growing. On the other hand, a longer lying-in period is thought to be important. Again, in addition to the physiological reasons for the practice, there are war-time and post-war conditions which have a bearing on it. All mothers are expected to stay in the hospital for 14 days after the birth of the baby, except when there is an acute shortage of hospital beds, when this period has been reduced to 10 days. When the baby is born at home (and a much higher percentage are born at home than in the United States), a midwife or district nurse visits twice a day for the first 3 or 4 days, then daily until the 14th day postpartum. This longer lying-in period is thought to be important in the establishment and maintenance of breast feeding even in normal times, and during the war was doubly important, for it was impossible to get friends or relatives to help at home, since all women had to work. Nor, as has been pointed out, is housekeeping ever "light" as it inevitably entails standing in one line after another and carrying heavy parcels.

Perhaps it is just these difficulties that have stimulated the local health authorities to extend, and in some areas initiate, a project which had been operating in a small way before the war. "Home helps," domestic workers employed by the health authority, are supplied as needed, either free or at small cost. This scheme has proved so useful that the new National Health Bill makes it a permanent function of health departments.

It is most interesting to see in operation here some of the projects which are still in the discussion or experi-

mental stage at home. The provision of "home helps" is one example; another was seen in a maternity hospital in the City of Luton. Numerous papers have been presented recently in American medical and public health journals regarding the desirability of placing the infant in the same room as the mother during the puerperium. Discussions of these papers have raised questions regarding the practical nature of such a plan and the difficulty of insuring the mother's rest. The maternity hospital at Luton takes care of all these questions. It is a delightful modern building with an atmosphere of quiet and cheer which is ideal for maternity care. At the time of visit, there were no more than 4 mothers to a ward, and each mother had her baby next to her. The babies are taken out at night, thus solving the sleep problem, and they may be, and often are, taken out in the daytime if advisable for either mother's or baby's health or peace of mind. Putting mothers and infants together is a common, though not universal, practice in England and as seen in this one hospital seemed ideal.

BREAST FEEDING

We talk a great deal about breast feeding at home, but they do more than talk about it in England. Again a small social factor exerts quite a large influence. Refrigeration is the exception, not the rule, here and the milk is apparently not of the same high quality as found in the larger cities at home (judging from newspaper accounts and comments of health officials); consequently it is harder to keep a formula fresh. However, these facts simply indicate why it is even more important to breast feed here than it is in America, and give added weight to the more fundamental reasons for breast feeding.

Much care and attention are given to establishing and maintaining breast feeding. As has been mentioned, the

midwife visits daily for 14 days, then the health visitor starts visiting on the 15th day if possible. Though, of course, the success of the physician and midwife and health visitor in maintaining breast feeding varies in different areas, it is generally much higher than at home and the expectation of the goal that should be reached is even higher. The pediatricians here deplore the fact that only 80 per cent of the babies born in hospitals are entirely breast fed at the end of 2 weeks. A pediatrician in a health department was heard to say that it was "appalling" that after 3 months only 50 per cent of the babies were breast fed and that this number had dropped to 40 per cent after 6 months!

In addition to the regular antenatal clinics there are special clinics for consultation regarding breast feeding for the more difficult cases, and some of the regular antenatal clinics are doing intensive work in this field and getting excellent results. A demonstration and lecture on breast feeding was attended at the British Hospital for Mothers and Babies, one of the clinics which are doing special work on breast feeding. The methods demonstrated there and results obtained are worth a separate article dealing with breast feeding.

The infant, after his first 14 days, continues to be the object of active health department interest. Ninety-six per cent of the infants born in 1944 were visited by health visitors. The health visitor aims to visit all infants regularly regardless of their attendance at clinics or any special problems. Actually, as the health visitor always has more work than she can do, she is apt to visit those who do not come to clinics more often than those who attend clinic regularly. The emphasis placed on this branch of health work by the health visitor is indicated by the fact that her work load is measured in terms of the number of births in her area, not in terms of the total population.

Articles analyzing maternal and infant deaths in relation to various obstetrical practices and socio-economic factors, including those produced by war, can be found in the literature. Numerous studies of the nutritional status of wartime England have also appeared in print, therefore no attempt has been made to present figures related to the practices observed. However, this observer can report that the infants and preschool children seen in clinics, nurseries, and in their homes certainly bear out the finding of the nutritional studies. As is well known, the nutritional status of children in England improved during the war and is now at a generally high level, and a healthier, huskier, firmer lot of babies this observer has never seen.

SCHOOL MEDICAL SERVICE

As startling as seeing food distributed in clinics, are the school treatment clinics. Minor ailment treatment clinics are part of the school medical scheme. They are usually located in a centrally situated school or in a separate building, and children are sent from other schools by the teachers or school nurses. The school system also operates free dental treatment clinics, eye clinics, and clinics for other specialties. Their services are available to all children in the schools equivalent to American public schools. There is no question whether a child is eligible for free care, or of sending him to his private physician, except of course for major illnesses. Apparently the shortage of physicians during the war, the 35 year old National Health Insurance scheme and system of "panel" doctors, has so influenced thinking on medical care that this prac-

tice is never questioned. There are few difficulties (except shortage of medical and dental personnel) in having a defect corrected once it is found. Sometimes parents do not agree to having the corrective work done, but apparently this is not frequent.

There are dozens of other things which clamor for space in this article, some just flashes from days in the field, some gleanings from conversation and discussions heard in the classroom, a lively meeting of the Royal College of Nursing addressed by the Minister of Health, a conversation in a bus with a health visitor, disconnected bits, but all thought provoking.

This opportunity to observe health work in another country has convinced this observer that there should be much more international visiting. It gives one a strong feeling of how closely bound the world is to see the identical problems in two different countries and meet almost the same wording in the descriptions of the difficulties involved in solving them. It is stimulating to see far advanced developments in certain directions toward which some of us have just taken the first steps, and it is refreshing to meet ideas so different from those voiced at home that one had not even recognized them as a legitimate point of view. Many English public health officials are planning to visit America and it is to be hoped that arrangements can be made for health officers and public health nurses from all parts of the United States to visit England.

A PROPOSAL FOR THE SOLUTION OF THE RECRUITMENT PROBLEM

Among the memorable features of the events of the Annual Meeting relating to the Merit System Unit, was an appraisal of public health recruitment problems by Dr. Wallace H. Wulfeck, Vice-President and Director of Research of the Federal Advertising Agency. This discussion preceded the Cleveland meeting and served as an orientation for the panel members who participated in the Merit System Unit session at the meeting. The analysis presented by Dr. Wulfeck represents a significant departure from the traditional approach to recruitment in public health, and it is felt that the point of view Dr. Wulfeck expressed has a special claim to the attention of the general membership.

In many major respects the problems a public health agency confronts in seeking personnel parallel the problems a manufacturer meets in seeking a market for his product—the product in the case of the public health agency being, of course, a “profession” or “jobs.” It is quite conceivable that the large experience of advertising agencies could be brought to bear on the problems of the professional agency. The research approach which underlies modern advertising procedures might very well be applied in an effort to develop methods for attracting qualified people to the field of public health. Such research customarily proceeds by way of four major steps: an analysis of the product; an analysis of the market; the development of the actual advertising by creative technicians on the basis of the findings of the two preceding steps; and, finally, pretesting the advertisement thus created to determine its effective-

ness before it is released on a wide scale.

Powerful as the advertising approach can be, Dr. Wulfeck nevertheless felt that the particular problems posed by the public health field could be dealt with most effectively as a public relations problem. Through such a program, an explicit awareness of the function of public health in this culture, its right to public support and approbation and to the best personnel available could be developed, with the dignity it deserves, among the public as a whole and among the professions from which public health personnel are drawn. The same basic motives activate professional people as activate people in general. They, like all other human beings, are driven by a longing for security, for self-expression, for adventure, and for fellowship. These drives are abundantly present in public health endeavors but this fact must be made known to the people who have to be reached if the pressing problem of personnel in public health is to be solved.

This task can best be accomplished, Dr. Wulfeck believes, through the appointment of a highly qualified public relations person to head a nation-wide program. Although the public health field consists of fairly autonomous groups throughout the country, the public relations program should be a single, unified project. Not only would this mean a more efficient and economical venture, it would also avoid the diversification and weakening of appeal which would result from a number of local programs. Such a person could so raise the status of public health in the public mind that legislators would say, “This is the kind of program we must sup-

port"; voters would say, "This is the kind of man we want to elect"; and people would say, "This is what I want to do; this is my life."

The urgency of the personnel problem in public health is great, the significance basic, and the need to solve it imperative. Unless, Dr. Wulfeck, says, public health leaders adopt the techniques

which have so indisputably demonstrated their effectiveness in business and industry, the solution to its recruitment problems will be postponed indefinitely. "You do not," Dr. Wulfeck concluded, "have a choice with regard to your course in this. You cannot afford *not* to undertake this project."

HEALTH LEGISLATIVE RECORD

Health Legislative Record, 1907-1946 is the forty-year chronicle of the outstanding health legislative program carried out in New York State by the state and local Committees on Tuberculosis and Public Health of the State Charities Aid Association. During the entire period Homer Folks has served as Executive Secretary of the Association, and George Nelbach Secretary of its State Committee on Tuberculosis and Public Health.

In 1908 the basic tuberculosis law of the state was drafted by the committee and its enactment secured; in 1909 the County Tuberculosis law was drafted and shepherded through the legislature.

The part of the committee and its citizen supporters in the Public Health Commission of 1913, and the public health laws resulting from it, in the passage of the county health unit law of 1921, in eliminating the "means test" for admission to tuberculosis hospitals, and in preparing the recommendations on which the Governor's Health Program of 1946 was based—these and many others are briefly summarized and constitute an impressive chronicle of citizen service.

Since the creation of the State Committee in 1907 it has served as the designated representative of the National Tuberculosis Association in New York State outside of New York City. It was the first of the state associations to receive permission from the national association to use funds from Christmas Seal sale

for the development of other lines of health work. It thus participated in the 1926-1930 diphtheria eradication campaign and is the up-state representative of the American Social Hygiene Association in the venereal disease control movement. The committee is the parent organization of 62 county and city tuberculosis and public health associations throughout the state.

CANCER CAPSULES

About the current size and shape of a woman's compact (the gadget women use for the hourly powdering of noses), and decorated not unlike it is the compact story of cancer, subtitled "Some Cancer Facts for Women." Put out by the New York City Cancer Committee, it tells in a bright conversational style the known facts about cancer and "is aimed to quiet some of your fears, answer some of your questions, and arm you with several life-saving tips."

Accompanying the "compact" are a number of leaflets about cancer of the various organs, ten cancer I.Q. questions, and a listing of the most common wrong information about cancer.

CITIZEN INTEREST IN THE HEALTH DEPARTMENT

The finance committee of the Pittsfield (Mass.) City Council has recommended that the city Health Commissioner's salary be increased from \$4,000 to \$6,000. In a weekly signed column in the *Berkshire Eagle*, the Secretary of the Pittsfield Taxpayers' Association

uses this as the starting point for citizen education in several matters. He analyzes the suggested new salary in relation to other city department heads; it is more than that of any other department head except the Superintendent of Schools, one-third more than the salary of the Public Works Commissioner, one-half more than the Mayor, and 60 per cent more than the Welfare Commissioner. In a further analysis of the five Massachusetts cities with medically trained public health officers, Mr. Ahern finds that Pittsfield's Health Officer is at no disadvantage in salary.

Then Mr. Ahern analyzes the work of the Health Department, pointing out the steady decline in the city's death rate and in the incidence of the common communicable diseases. He recognizes that health ranks with schools and public works in vital public services. But—and this is the warning that should be noted by public health workers in their quite proper current demands for higher salaries—Mr. Ahern in mentioning the Health Department's apparent lethargy in certain matters of building codes, water pollution, and others, says "Communities will pay off when health officers lift their eyes to new fields to conquer, visible to the average man even now." A neat job of objective analysis.

A COMMUNITY MEETS ITS OWN NEEDS

Credit Lines is indebted to the Berkshire District Health Officer, Dr. Charles E. Gill of Pittsfield, Mass., for copies of the *G. E. Pittsfield Apparatus Works News*. These tell the story of how employees of the local General Electric plant raised enough money for three iron lungs plus \$6,000 for the local chapter of the National Foundation for Infantile Paralysis.

It all began with five polio cases, one fatal, one paralyzed, and three recovered, in one local Boy Scout camp in July. On August 9, the *News* outlined the campaign plan by which it was

hoped each General Electric employee would contribute at least \$1. The goal was three iron lungs, cost \$4,800. On August 23 the *News* announced a total of nearly \$11,000 in gifts.

PUBLIC HEALTH EDUCATION IN INDIANA

Indiana's *Monthly Bulletin* of July, 1946, uses a series of simple but effective charts to educate Hoosiers in the need for extending their health services. The figures point out, for example, that the death rates from four communicable childhood diseases and from typhoid fever as well as from all enteric causes, though in each case lower than the average for the United States, are higher than in any of the four neighboring states of Illinois, Michigan, Ohio, and Wisconsin. In no one of the measures of community health—cancer mortality, tuberculosis mortality, maternal or infant mortality—is Indiana at the top of the list of these five states. In per capita appropriation for health services Indiana is fifth from the bottom of the 48 states, in expenditures for local health units it is at the bottom of the five states, with less than one-third the expenditures of its nearest competitor, Illinois. As to state expenditures, it is lower than any of the five, except Ohio.

The moral: "How badly do we need full-time local health departments! They would cost so much less than disease. . . . Adequate public health administration for a given community will cost annually about one dollar per capita, the cost of two cocktails, or a fairly good tie. . . . How ridiculously small that seems."

BLUEPRINT FOR REHABILITATION CENTERS

The fourth of the publications of the Baruch Committee on Physical Medicine is a *Report on a Community Rehabilitation Service and Center*. This booklet is the final report of the Subcommittee on Civilian Rehabilitation

Centers. The foreword states that it has been prepared "in the hope that it will be of aid to communities, medical schools, civic groups, or any organization interested in establishing community rehabilitation centers."

The plans have been derived from the experience in the armed forces. They represent a basic guide and must be modified to meet specific needs of the individual community. The report has been prepared to meet requests for information on rehabilitation centers that have come from all over the world.

Available from The Baruch Committee on Physical Medicine, 597 Madison Avenue, New York 22.

THE RIGHT—SO RIGHT—ANSWER!

A mayor of a midwestern town recently was visited by a delegation with the request that he reopen a red-light district, closed during the war. He told them: "Gentlemen, I'll reopen that district if you permit your own daughters to staff the houses. Somebody's daughters would have to be placed there. I don't want the personnel recruitment on my conscience." The delegation left in silence. "The Prostitution Racket Is Back" by Albert Deutsch in *The American Mercury*, September, 1946.

The New York State Committee on Tuberculosis and Public Health sends out this perfect answer to its local associations, suggesting that it be used in bulletins and news letters, in talks and interviews.

DULUTH'S ANNUAL REPORT

The 1945 report of the Duluth, Minn., Health Department is its 49th. It takes justifiable pride in a perfect maternal mortality score—no deaths from diseases or complications of pregnancy and child bearing. "What has been done before may be done again!" says the report.

It also takes pride in the history of its diphtheria prevention program.

Twenty-five years ago in 1921 there were 204 cases and 11 deaths. In 1933 began a ten year period with neither resident cases nor deaths (four non-resident cases and one death during the period). In 1943, following the trend in other areas of the country, four cases appeared, in 1944, 22 and in 1945, 18. However, only two deaths occurred in these three years. The report does an excellent job of interpretation of this trend, of the four to six month period required for diphtheria injections to attain a satisfactory level of immunization, and of the timing factors in planning a city-wide immunization campaign.

The margin illustrations in the report are taken from the Association's pamphlet "What to Tell the Public About Health."

COMMUNITY EDUCATION IN COMMUNITY NEEDS

The American Hospital Association met in Philadelphia in October. This, together with the passage of the Federal Hospital Construction Act, inspired the Chamber of Commerce to devote a large part of the October *Philadelphia* to a discussion of the hospital problem in that city, with particular emphasis upon the Blue Cross plan.

With appropriate historical notes (Ben Franklin was the first clerk of the first Board of Hospital Managers in 1751), and with excellent photographs, it tells the story of the city's existing hospitals, sources of their income, their contributions to medical science, such as Bryn Mawr Hospital's part in developing the dried blood plasma methods, and finally the story of Blue Cross—its growth, its effect upon the stability of hospitals, and the degree of its acceptance by the public and the medical profession. This has been called "a unique effort to bring to the citizens of our community an awareness of the complexities which

must be understood by everyone if Philadelphia's needs are to be met."

FIFTY YEARS OF HOFFMAN-LA ROCHE

Hoffman-LaRoche celebrates its 50th birthday, and the 10th birthday of the *Roche Review* (Roche Park, Nutley 10, N. J.), with a Tenth Anniversary issue of the Review. It summarizes the progress in medicine, and in endocrinology during the years 1936-1946, of the progress at Roche itself during these years, a brief history of the firm including pictures of the Basle, Switzerland, plant where 50th anniversary festivities were recently held, as well as past and present pictures of Roche Park in New Jersey. An interesting report without blatant ballyhoo.

JOINT WATER SUPPLY SYSTEM FOR TWO MICHIGAN CITIES

Evidence piles up of coöperation among communities in providing citizen services. The latest comes out of Michigan where the cities of Saginaw and Midland, with populations of 81,000 and 10,000 respectively, have entered into an agreement to build and operate jointly a water supply system, the annual operating costs to be allocated on the basis of the amount of water used. Its management will be vested in a six member board consisting of the city manager and two other representatives of each city.

SUMMER INTERNSHIPS FOR MEDICAL STUDENTS IN HEALTH DEPART- MENTS IN MISSISSIPPI

Summer Internships in a Public Health Program for Medical Students, describes a demonstration program arranged by the Mississippi State Board of Health in the summer of 1946. Twelve sophomore and junior medical students from four coöperating medical schools were selected on the basis of references and their expressed interest in public health. For the period of

their internships they were given subsistence allowances. A one week introductory training course was conducted at the central offices of the State Board of Health in Jackson by Felix J. Underwood, M.D., and his staff. The students were then assigned for two months to county health departments that offered a suitable program. Here they not only observed the operation of the county health units but also participated actively in the work of the departments, principally in the various clinics.

Comments of the students and the participating health officers quoted in the booklet indicate that this project, which was planned "to determine the value of two or more months' actual experience in a state-wide public health program," was a successful experiment. Plans are already in progress to repeat and to expand the program of summer internships in Mississippi in 1947. Applications for participation are being received by Felix J. Underwood, M.D., Executive Officer, Mississippi State Board of Health, Jackson 13, Miss.

For the benefit of those who are interested in field training it would be interesting to know how the schedules were arranged as, for instance, the amount of time spent with various members of the health department staff, number of clinic sessions attended, and the methods of introducing the students to community programs.

POLLUTION ABATEMENT

The abatement of the pollution of streams and inland waterways is the chief topic of concern in the October, 1946, issue of *Sewage Works Engineering*. In anticipation of the introduction of a new bill in the 80th Congress to replace HR 6024, "the compromise bill, which failed to compromise"—information relative to current state pollution efforts is presented.

"National Round-Up of Pollution Abatement Program" is one of the articles

appearing in the issue mentioned above. It summarizes the replies of 35 state sanitary engineers to questions concerning: (1) official pollution abatement units and their programs; (2) new pollution legislation; (3) the attitude of industry toward pollution abatement; (4) state participation in joint pollution abatement activities, and (5) present sewage treatment works construction plans. The text of the replies of 31 of the state engineers is also included.

INTRODUCING THE "COMMENTATOR"

With Vol. 1, No. 1 of the *Health Commentator* in October, 1946, Washington was added to the list of states whose health departments publish a monthly bulletin of news about state health activities. In the first issue Arthur L. Ringle, M.D., State Director of Health, outlines the purpose "to interpret new developments in public health and to make you better acquainted with the work of your local health department and the State Department of Health."

This issue also reports plans for the organization of a Bellingham City-Whatcom County full-time health department as the result of action by the city council and county commissioners. This area of more than 60,000 persons is currently served by two part-time health officers.

HOSPITAL COUNCIL

Credit Lines welcomes the new monthly *Bulletin of the Hospital Council of Greater New York* (370 Lexington Avenue, New York). Although the September, 1946, issue is Vol. 2, No. 1, it is actually a new bulletin, its only other issue being in 1944, after which it became a wartime casualty. This new first issue reviews the progress in the development of a master plan for hospital facilities in metropolitan New York and gives a brief summary of the Hospital Construction Act in non-technical

language. John B. Pastore, M.D., is Executive Director of the Council, Haven Emerson, M.D., is Chairman of its Planning Committee and serves on the editorial board of the *Bulletin*.

HOME RULE IN HEALTH

Under this title the October *Georgia's Health* (12 Capitol Square, Atlanta 3) reports that eight multiple county health units have been organized since January 1, 1946, thus providing local health service to 400,000 persons. More than two-thirds of the state's population is now protected by full-time local health department service. Continues the report "Personnel shortages are more acute now than they have ever been. Since personnel is scarce, effective distribution of that remaining has been a paramount objective."

THE EVALUATION SCHEDULE IN OTHER FIELDS

A recent correspondent proposes that the *Evaluation Schedule* might be used as a pattern for evaluation in the field of public welfare. If among our readers there are uses of the *Evaluation Schedule* in other fields outside of public health, the editors would be pleased to know about them.

URUGUAY'S FIRST HEALTH CENTER

In March, 1946, Uruguay's first health center was inaugurated in Fray Bentos, a municipality of about 18,000 persons. Fray Bentos is a meat packing center and has an excellent fresh water port on the Uruguay River. The story of this health center, a coöperative venture with the Institute of Inter-American Affairs, the community organization preceding it, its activities and staff, is told in the September *News Letter* of the Health and Sanitation Division of the Institute of Inter-American Affairs (Washington 25, D. C.). Among its present unusual features is a six month course in nursing

for local student nurses, in order to meet the nursing shortage.

IMMUNIZATION IN AURORA, ILLINOIS

The *Illinois Health Messenger* (Springfield, Ill.) of August 1, 1946, reports on the diphtheria and smallpox immunization program in the Aurora public schools. The chief elements in the protection of nearly 90 per cent of school children are the coöperation of medical, public health, and school agencies, and the regularity with which the program is carried on each year. In this program only those unable to pay are given free service; the physicians participating in the program are reimbursed from the \$1.50 charge per child, for which a complete series of inoculations against diphtheria and smallpox are provided.

TIPS ON THE USE OF CARBON

TETRACHLORIDE

"How to Use Carbon Tetrachloride Safely," is further inscribed, "Tips to the Foreman." Those titles of the leaflet prepared by the Safety Research Institute, Inc., New York City, describe the contents of the four page folder adequately. If you work with carbon tetrachloride you probably would appreciate seeing a copy of these Tips.

USE OF RODENTICIDE 1080

Here is a timely leaflet published by the Texas Water and Sanitation Research Foundation, Austin, Tex., that should answer those questions about the new rodenticide "1080." "Instructions for Use of Compound 1080 as a Rodent Poison," tells briefly how to use the poison, limitations in its use, precautions in handling, and what to do when those inevitable accidents result in the wrong animal (man) getting the poison.

CANCER EDUCATION IN SCHOOLS

The American Cancer Society (350

Fifth Ave., New York 1) has a set of cancer education pamphlets for schools known as School Set "A." It includes instructions for building a cancer control school program, a bibliography, and much material to stir the interest of youth. *Changing of the Guard*, for example, starting with the historical guards at Buckingham Palace, inspires the youngster to guard his parents with knowledge about cancer; *Health Heroes* is a moving short biography of Marie Curie; *Cancer: A Challenge to Youth* is an attractive classroom guide to the study of cancer; *Youth Looks at Cancer* is a Textbook for Colleges and High Schools. These and others included in the packet make for a well balanced study project which introduces young people early to one of the present-day most serious and most puzzling medical problems.

CANCER EDUCATION IN LABOR UNIONS

The New York City Cancer Committee last spring began a vigorous campaign of cancer education in labor unions. By getting the coöperation of the Central Trades and Labor Councils of both national unions, and the Joint Boards or Councils of local unions in a particular union it has been able to place its educational material in many union headquarters and meetings and to plan for physicians' lectures on cancer to union groups. This is a channel for health education that other groups could use with profit.

WORTH ACQUIRING

With the publication of *Cancer Facts* the Health and Welfare Division of the Metropolitan Life Insurance Company ends its first year of an extensive educational program on cancer. *Cancer Facts* is an exhibit first displayed at the July, 1946, meeting of the American Medical Association. It consists of 10 charts, 21 x 30 inches, in two colors. Copies are available for teaching and

exhibits (Health and Welfare Division, Metropolitan Life Insurance Company, 1 Madison Avenue, New York 10).

This exhibit reproduced in booklet form, is called "Cancer Facts." The supply of the booklet is limited to reference use or for study or promotional programs.

OKLAHOMA'S MERIT SYSTEM ANNUAL REPORT

The 1945-1946 annual report of the Oklahoma Merit System of Personnel Administration represents a departure from the usual method of reporting activities. Designed to attract candidates and potential workers for public health, welfare and employment agencies, it presents in pictorial and graphic form, through cartoons and the use of short, terse, factual statements, the steps through which an applicant goes in order to secure a position. It presents the principles of the merit system of personnel administration, its history (on one page with two cartoons), the application and examination process, and the various benefits which are a part of government service. The veterans' section is particularly well done. The preference given for veterans is presented clearly and concisely, positions for veterans in public welfare are listed, and a one-line war biography is given for 49 veterans who have returned to their work.

Major vocations are listed under a picture of the home office of each agency, and "common agency jobs" are listed separately. The work history under the merit system of one employee is carried under her photograph, and three outstanding examination candidate are pictured.

The Merit System Council has two pages listing major actions taken during the year with regard to personnel.

For the person interested in the classification of activities carried on by the Council, the section on examinations, activities affecting personnel, including certifications, will be of interest. The unit demonstrates its interest in self-analysis by the studies being carried on relating to item analysis of examinations, analyses of oral examinations, tenure of employees, non-appearance of applicants, personnel status and costs.

This attractive pamphlet is timely in view of the expanding post-war health programs and the need for public workers.

CORRECTION

The correct address for Community Service Society as mentioned in November Credit Lines (p. 1328) is 105 East 22nd, New York 10, N. Y. The correct price of the latest revision of its Guide for Public Health Nurses: Tuberculosis is 10¢ plus postage.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted. All books reviewed in these columns may be purchased through the Book Service.

The American Hospital—By E. H. L. Corwin, Ph.D. New York: The Commonwealth Fund, 1946. 226 pp. Price, \$1.50.

Those engaged in the field of hospital administration, as well as the public at large, have been limited in the availability of informative material on this subject. As a matter of fact, but two or three books of significant value have been published during the past quarter of a century which could justify being considered as a text and reference at the disposal of those concerned with hospital care. Anything, therefore, which contributes to the literature in this field has received a most hearty welcome.

Dr. Corwin has assembled, in readable form, some interesting and historic data on the development of the hospital structure in the United States, the changes which have taken place in a comparatively short span of time, and has emphasized the important reasons which have been responsible for the increasing popularity and the rapid growth of our hospitals. Chapters are devoted to staff organization, the out-patient department, the hospital as a teaching institution, and particularly appropriate space is given to a review of the past and the prospects of the future. In connection with the latter phase, the place of convalescence, chronic care, domiciliary treatment of the sick, as well as an estimate of post-war hospital needs, receive fitting recognition.

This book will be of great interest and value to all who are interested in the whole subject of hospital service for the American people and who may desire, in reasonable digest form, facts and figures dealing with this important phase of essential community service.

CHARLES F. WILINSKY

Cities Are Abnormal—Edited by Elmer T. Peterson. Norman, Okla.: University of Oklahoma Press, 1946. 263 pp. Price, \$3.00.

This book, a symposium by a dozen authors, many of them well known, presents a case for "decentralization" of cities. One chapter, by a physician, is on "biological truths and public health." In spite of many undocumented assertions or scientific half-truths in this and other chapters, there is much relevant and valuable material in the volume on the desirability of having the industrial worker tied to the soil. Many aspects—including "the atomic threat"—are touched on, with perhaps too little emphasis on blighted areas and the slums. The tenor of the book is unduly optimistic. It would appear that the evils will be righted "under the auspices of individual initiative, encouraged by such a governmental policy as is likely to create the appropriate climate and ecology for decentralization."

ROLLO H. BRITTEN

Essentials of Pediatrics—By Phillip C. Jeans, A.B., M.D., Winifred Rand, A.B., R.N., and Florence G. Blake, R.N., M.A. (4th ed.) Philadelphia: Lippincott, 1946. 627 pp. Price, \$3.50.

Here is an excellent book for schools of nursing where public health nursing is being incorporated into the basic curriculum. The relation of the child to the family and what constitutes complete nursing care is stressed repeatedly. "Situations for Further Study" encourage the nurse to outline instructions for the mother giving care in the home. Chapter V—"The Child Health Conference as a Means of Guidance" is recommended for the public health nurse as well as the nurse in the out-patient de-

partment of the hospital for whom it was written.

The contents have been rearranged into five units as suggested in the curriculum for schools of nursing prepared by the National League of Nursing Education. The description of the growth and development of the normal child precedes the discussion of the specific diseases of children and the nursing care recommended for each.

The many illustrations and arrangement of text material into double columns with appropriate headings make for easy reading. A glossary and up-to-date bibliography enhance the value of the book for the undergraduate and graduate nurse. FLORENCE MANLEY

The Forces That Shape Our Future—By Clyde Eagleton. *New York: New York University Press, 1945.* 200 pp. Price, \$3.25.

Things move so fast in the international field that it is unusual to find a book published in 1945 which is still valuable in 1947. Professor Eagleton's James Stokes Lecture is an exception to the general rule, in part perhaps because the Commission for the Study of the Organization of Peace (with which Professor Eagleton is connected) is playing so influential a part in shaping national policy. In any case, this compact volume is well worth reading for those who want to face wisely the problems of the future.

The major thesis of Professor Eagleton's book is that the increasingly complex interrelationships of the modern world create an essential and vital antithesis between "rugged individualism" and the necessity for coöperative effort—both on the national and the international stage. The solution can only be found by dispassionate thinking and by the working out of effective compromises which will save the major values of both viewpoints. "The unbearable pressure of modern war" makes the discovery of

such solution most immediate; and Professor Eagleton dedicates his book "to my son, who also must fight because of mistakes of his elders." He outlines clearly the essentials of an adequate program of international coördination, and the sacrifices we must be prepared to make to render such an organization effective. He says in his final chapter, "the unknown wilds of this continent did not daunt us as we pushed its frontier back; the risks of huge business undertakings and organization have never caused us to hesitate; we are pioneers today in great new fields of science and technical development. The blood of our fathers is still in us, and it surges forward to face the new opportunities that lie ahead."

C.-E. A. WINSLOW

Diabetic Care in Pictures—By Helen Rosenthal, B.S., Frances Stern, M.A., and Joseph Rosenthal, M.D. *Philadelphia: Lippincott, 1946.* 150 pp., 137 illus., 4 in color. Price, \$2.00.

If every diabetic could own this book, the time normally spent by physicians, nurses, and dietitians in teaching diabetics how to take care of themselves would be greatly reduced. The patients would have constant access to simple but accurate information to guide them in everyday living with others and with their disease. Following the physician's diet prescription would be fun, for diabetics can so easily have wide choice of food and still stay within their prescription. Every step in diet control, use of insulin, follow-up checks on urine, and in the care of their bodies is profusely illustrated, as well as simply described. The reviewer regrets that, in the table showing suggested food allowances, niacin allowance is given in milligrams needed per day, while in the pages showing relative values of foods as sources of niacin, the standard of comparison is expressed in micrograms.

MARTHA KOEHNE

The Venereal Diseases—A Manual for Practitioners and Students— By James Marshall. New York: Macmillan, 1946. 348 pp. Price, \$4.50.

This book is intended as a manual or textbook for general practitioners and medical students. It is written by an English physician for British medical consumption and this must be borne in mind by the American reader.

The control of the venereal diseases through treatment has undergone remarkable change and particularly in the interim between the time the book was published in 1944 and the present. The use of sulfonamides is stressed in the treatment of gonorrhea rather than penicillin, which is mentioned briefly in the discussion. Rather elaborate treatment schedules with arsenic and bismuth are recommended in the treatment of syphilis with no discussion of the rôle of penicillin.

There are excellent diagrams and pictures throughout the text and these contribute markedly to the readability of the book. An excellent chapter is included on practical instructions as to procedures and technic in office practice.

There is little of the philosophy of the public health control of the venereal diseases and the rôle of the private practitioners in the control program.

There are several points of view expressed by the author which may be debatable, but differences can be resolved by an understanding of some fundamental differences of approach to venereal disease control in Britain and in the U. S. A.

This book should be a valuable addition to the well-rounded library of the American venereologist. J. R. HELLER, JR.

New Worlds in Medicine—Edited by Harold Ward. New York: McBride, 1946. 689 pp. Price, \$5.00.

The lay editor often discovers gems

of medical writing which never find their way into technical journals. Editor Ward has assembled a sparkling collection of such gems in this anthology. It is a worthy companion to his recent anthology, *New Worlds in Science*. Written for the layman, these choice articles have been selected with remarkable discrimination so that technical material is presented in everyday language.

The editor has received inspiration from lectures to the laity published by the New York Academy of Medicine, but he has also made a fruitful search of many books and periodicals not usually seen in physicians' libraries. Excellent continuity has been maintained partly by choice of subjects and partly by the editor's introductory remarks preceding each article. By these means he has been able to display the progress in a given field within its proper historical setting. He has also achieved a balance between technical and social progress with just the right emphasis on preventive medicine. Trends in social medicine appear inevitably attached to progress in technical medicine while technical material is presented with simplicity and interest, but without melodrama. At the conclusion of each subject the reader is left with the feeling that he has learned much about a subject he thought he knew and about which more should have been written.

All of the contributors are eminent in their special fields, yet they write with a simplicity that comes from complete familiarity with the subject. For the sake of the lay reader it is unfortunate that the biographical sketches of contributors are not stronger, and that they are not inserted as a preface to each article. To point out the most outstanding contributors in this anthology would be to detract from an appreciation of all the gems in a total setting.

This is a book that will bring much satisfaction to the health officer and his

staff. For the health educator it will be a stimulating source of reference and of inspiration.

CHARLES E. SHEPARD

Free Medical Care—Compiled by Clarence A. Peters. The Reference Shelf, Vol. 19, No. 3. New York: H. W. Wilson Company, 1946. 378 pp. Price, \$1.25.

This is a compilation of material on national health insurance. There is a fairly good selection of pro and con opinions with scrupulous adherence to the principle of giving both sides equal space. The title of the volume is most unfortunate since the point at issue is not "free medical care" but prepaid medical care. This confusion is evident in the volume itself and reflects the popular misunderstanding engendered by the use of emotionally charged words like "socialized medicine."

While the book is of little value to the serious student of medical care problems, it may be useful as an introduction to the subject. Its greatest use will be the one for which it is evidently intended, as a convenient reference and debating manual. MILTON TERRIS

Water Bacteriology—By Prescott, Winslow, and McCrady. New York: Wiley, 1946. 368 pp. Price, \$3.50.

Water bacteriologists welcome the revision of this reference book, which for

forty years has been a necessary part of the equipment of the water laboratory. During the fifteen years since the appearance of the previous edition important advances have been made in bacteriologic procedures in sanitary water analysis. While *Standard Methods for the Examination of Water and Sewage* gives the laboratory techniques, it is necessary to interpret the results, and this volume gives the basis for the interpretations.

The revision has been made by the junior author with commendable results. The entire book has been rewritten. The most notable changes are those in connection with the coliform organisms. These chapters are excellently written and all-inclusive. Although some of the methods described are only of local significance, they are and should be included in an adequate discussion.

At first the reviewer wondered at the continued inclusion of tabulated data carried over from earlier editions, but more careful study convinced him that these tables are not only just as good illustrative material as when first published, but also that many of them have never been duplicated. Where new material is available, it has been substituted.

The water bacteriologist and the sanitary engineer again have available an authoritative treatise.

JOHN F. NORTON

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Hygiene and Sanitation in Company Towns—Have you wondered why so little is written about those radical departures from industrial practice, the miners' welfare and medical care funds? Well, here are some illumi-

nating papers you can't afford to miss if you have any interest whatever over and above your own two-by-four job. Incidentally, you'll get some inkling of the reasons the discussion may have been soft-pedaled.

BOONE, J. T. New Horizons in Industrial Health and Welfare (and two related papers). J.A.M.A. 132, 13:755 (Nov. 30), 1946

This Will Leave You Chastened—Mental hygiene seems to be on every health worker's tongue these days. Before you go off the deep end, too, you might read this discussion of psychoneuroses, psychoses, and psychopathic personalities, just to see how shallow you'll find the water when you dive in. Does a psychoneurosis ever develop into a psychosis? This is only one of a dozen unanswered questions you'll find here.

BOWMAN, K. M. Modern Concept of the Neuroses. J.A.M.A. 132, 10:555 (Nov. 9), 1946.

Where Cruelty Was a Fine Art—"The fruits of experience as prisoners of war in Japanese hands, though abundant, were exceedingly bitter." So begins a stomach-turning account of conditions in Java and Siam prisoners' hospitals. This paper would make salutary reading for those in danger of becoming maudlin over the news accounts of the little people's idolatry of McArthur.

DUNLOP, E. E. Medical Experiences in Japanese Captivity. Brit. M. J. 4474:482 (Oct. 5), 1946.

Good News about Mumps—Pathogenicity of mumps virus decreases on continued passage in the egg, but the antigenicity appears to be maintained—for monkeys, and possibly, for man.

ENDERS, J. F., *et al.* Attenuation of Virulence with Retention of Antigenicity of Mumps Virus after Passage in the Embryonated Egg. J. Immunol. 54, 3:283 (Nov.), 1946.

Trends of Sickness Absenteeism—Sickness and non-industrial accident rates (lasting 8 days or longer) have risen regularly, culminating—in 1945—in male and female rates that have not been equalled. Because of notable in-

creases in nonrespiratory-nondigestive diseases, the frequencies of rheumatic, nervous, circulatory and genitourinary diseases are shown for each sex. There's a lot more.

GATAFER, W. M. Sickness Absenteeism among Male and Female Industrial Workers during 1945, With a Note on the Respiratory Epidemic of 1945-46. Pub. Health Rep. 61, 45:1620 (Nov. 8), 1946.

Not a Substitute for Proved Treatment—More good—though guarded—news about streptomycin and tuberculosis. It suppresses rather than eradicates TB, but results are encouraging. Large doses are required over a 2 to 4 month period, so treatment should not be started unless a sufficient supply is in sight, and patients who are doing all right without it shouldn't get it.

HINSHAW, H. C., *et al.* Treatment of Tuberculosis with Streptomycin. J.A.M.A. 132, 13:778 (Nov. 30), 1946.

Fluorine Applied to Children's Teeth—During the third year of this study, the permanent teeth attacked were 22 per cent less for the treated than the untreated. This difference is substantially less than for the first two years of this Minnesota research.

KNUTSON, J. W., and ARMSTRONG, W. D. The Effect of Topically Applied Sodium Fluoride on Dental Caries Experience. Pub. Health Rep. 61, 47:1683 (Nov. 22), 1946.

A Plan for Minneapolis—As with most problems, the nearer tuberculosis control comes to being established on a scientific basis, the more clear-cut become the differences of expert opinion. Here you will find a forcefully expressed viewpoint at variance with other workers in the field. It will do you good to read this paper with an open mind, whether or not you are immediately concerned with tuberculosis.

MYERS, J. A. The Establishment and Use of Fundamental Procedures in Tuberculosis Control. Pub. Health Rep. 61, 41:1563 (Nov. 1), 1946.

Good Advice for the Deafened—

If you want a hearing aid consult an otologist first, try a number of makes at a Hearing Aid Clinic, try the aid in both quiet and noisy places, buy the instrument you like best, and use it full time, know when to turn it in for a new model.

NASH, C. S. Artificial Aids to Hearing. *Am. J. Nurs.* 46, 11:763 (Nov.), 1946.

Not To Be Missed—

For the good of his own soul, everyone in public health should read this caustic dissertation on respiratory infections—colds, sore throats, grip, virus pneumonias, and the influenzas. Essentially the discussion boils down to this: nothing we teach others to use or use ourselves does good in curing virus infections; advertised cold cures are not worth the powder to blow them you-know-where; and (aside from teaching people the worthlessness of most of the so-called treatments they have come to believe are good for them) there is precious little to be done at present about viral infections, except to go to bed. Influenza A and B are, of course, other matters.

REIMAN, H. A. Viral Infections of Respiratory Tract. *J.A.M.A.* 132, 9:487 (Nov. 2), 1946.

Profound Words Department—

"Until recently what men thought about cancer depended on how ingenious they were, they had not enough facts to constrain them. It has taken decades to trace the natural history of the disease and to uncover the complexities of its occurrence, but now it looms in sharp

outline. . . . This is well, for the problem has turned out to be larger than anyone knew."

ROUS, P. Concerning the Cancer Problem. *Am. Scientist* 34, 4:329 (July), 1946.

It Works on American Rabbits, Too—

Antireticular cytotoxic serum was prepared according to the technics evolved by the Russian researchers and its effects were tested upon experimentally produced fractures in rabbits. Much to your surprise, the stuff really did stimulate the healing process.

STRAUS, S., *et al.* Studies on Antireticular Cytotoxic Serum. *J. Immunol.* 54, 2:151 (Oct.), 1946.

Respect for the Individual—

"It is the increasing practice today among pediatricians who are mindful of all the developmental needs of infants to instruct mothers to nurse their own babies and to nurse them when they are hungry." That seems to be enough to tell you about this paper.

TRAINHAM, G., and MONTGOMERY, J. C. Self-Demand Feeding for Babies. *Am. J. Nurs.* 46, 11:767 (Nov.), 1946.

Health Education and Medical

Care Needed—Though Negro maternal mortality rates have been nearly halved in the last two decades, they are still two and a half times the death rate of white mothers. Why? Is it a matter of biologic inheritance, some essentially different obstetrical problem, or contrasting situations of economic and social heritage? You'll find answers here.

WILLIAMS, P. F. Maternal Welfare and the Negro. *J.A.M.A.* 132, 11:611 (Nov. 16), 1946.

ASSOCIATION NEWS

RESOLUTIONS

The following Resolutions were unanimously adopted by the Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 13, 1946.

1. MILTON JOSEPH ROSENAU

The Governing Council records with profound sorrow the passing of the President-Elect of the Association, Milton Joseph Rosenau, on April 9, 1946.

For nearly 40 years a member of the Association and a Charter Fellow, Dr. Rosenau served the Association with unique competence and distinction. He served as a member of the Governing Council from 1930 to 1936, as Chairman of the Epidemiology Section in 1939, and as a member of the Sedgwick Memorial Medal Committee from 1933 to 1937. In 1934 he was awarded the Sedgwick Memorial Medal for distinguished service in public health.

As Fellow, as Committee Member, as contributor to the *Journal*, Dr. Rosenau's preeminence as teacher, distinguished author, epidemiologist, and administrator was brought to the service of the Association and the public health ideals for which it exists. We shall long miss the inspiration of his wisdom and of his humanity.

RESOLVED that this resolution be spread upon the minutes, that copies be forwarded to Dr. Rosenau's family and to the University of North Carolina, and that it be read as the first item of business at the Opening General Session of the 74th Annual Meeting on Tuesday evening, November 12.

6. L. L. LUMSDEN

The Governing Council has learned with deep regret of the recent death of Dr. L. L. Lumsden.

Long a member of the Association and a pioneer in the field of public health,

he was an outstanding figure in epidemiological research and in the development of rural health administration.

During his active professional life extending over a period of more than 40 years, he contributed generously to sanitary science and to legislative enactment in the interest of public health. Through his knowledge and enthusiastic devotion to the fundamental principles of the work which he loved, he was a continuing inspiration to his associates and was responsible for many engaging in a public health career.

Those who knew him and received his kindly guidance will cherish his memory as long as they live.

RESOLVED that this resolution be spread upon the minutes, that copies be forwarded to Dr. Lumsden's family and to the United States Public Health Service, and that it be read at the Second General Session of the American Public Health Association held in Cleveland, Ohio, November 13, 1946.

7. IN MEMORIAM

RESOLVED that it is with a sense of irreparable loss that the American Public Health Association records, since its last Annual Meeting, the death of one hundred thirty-eight Fellows and members, the names of whom constitute a part of this resolution.

 Margaret B. Wilson, Washington, D. C., Elected member 1915
 Verne L. G. Wilt, D.D.S., Los Angeles, Calif., Elected member 1940

8. SCHOOL LUNCH PROGRAMS

WHEREAS, the great stimulus to school meal programs provided through the passage of the National School Lunch Act of 1946 does not of itself assure that the potential benefits of school meals will accrue to all children attending school, be it

RESOLVED that the American Public Health Association encourage the establishment of school lunch programs according to accepted standards; encourage efficient administration of school meals from all aspects, nutritional, sanitary, educational, and economic; and encourage carefully controlled studies of the effect of school meals on nutritional status and home feeding practices.

9. EQUAL OPPORTUNITY FOR PUBLIC HEALTH PERSONNEL

WHEREAS the public health profession is keenly aware of the fact that disease knows no boundaries of state or nation, of economic status, of race, color or creed, and

WHEREAS, one of the fundamental objectives of the Association is to foster a high professional standard for all workers in public health and to strive for the recognition of workers solely on the basis of their professional qualifications and capabilities, therefore be it

RESOLVED that the American Public Health Association endorse the thesis of equal opportunity for everyone in the field of public health and recommends a program of equal opportunities for employment, professional advancement and salaries in all activities of the public health profession regardless of race, color, or creed.

10. APPRECIATION TO THE COMMITTEE ON CONSTITUTION AND BY-LAWS

RESOLVED that the American Public Health Association express its grateful appreciation to the Committee on Constitution and By-Laws for the spirit in which it has undertaken the very important and time-consuming task of revision of the Constitution and By-Laws. Specifically, appreciation is expressed to members of the committee: Drs. Haven Emerson, Franklin Foote, Charles E. Shepard, and especially the *Chairman*, Dr. Edward S. Godfrey, Jr.

11. APPROVAL OF FORMATION OF THE WORLD HEALTH ORGANIZATION

WHEREAS, the attainment by all peoples of the maximum in health is the ultimate goal of all public health workers and,

WHEREAS, uncontrolled disease, espe-

cially communicable disease, in less favored countries is a common danger, and

WHEREAS, in many parts of the world there has been continued physical, mental, and social illness, and

WHEREAS, the attainment of world peace is to a considerable extent dependent upon the attainment of world health, and

WHEREAS, 61 countries have recently signified their interest in the development of the World Health Organization by the signing of the Constitution presented to the World Health Conference in New York City in July, 1946, therefore be it

RESOLVED that the American Public Health Association go on record as giving wholehearted approval to the formation of the World Health Organization and urge the immediate ratification of the Constitution of the World Health Organization by the Congress of the United States of America and by appropriate legislative bodies of those countries that have not already taken such action.

12. DEVELOPMENT OF BLOOD DONOR PROGRAMS

WHEREAS, human blood is assuming an increasingly important place in the treatment of disease and the saving of life;

WHEREAS, the value of this product is in proportion to its availability and adequacy of supply in any given locality;

WHEREAS, the American National Red Cross is prepared to assist in the creation and maintenance of state-wide and community blood donor pro-

grams to make human blood available to all elements of the community through members of the medical profession;

WHEREAS, such programs are undertaken only under the sponsorship of official health departments, medical societies, or hospital agencies; and

WHEREAS, concerted community effort is essential for the success of the blood donor program, a program which will be of immeasurable assistance to the medical profession in meeting the health needs of the people; now, therefore be it

RESOLVED that the American Public Health Association go on record as endorsing the participation of the American National Red Cross and its recognized chapters in state-wide and community blood donor programs; and be it further

RESOLVED that the American Public Health Association encourage the development and maintenance of state-wide and community blood donor programs through which human blood may be made readily available without charge for the product to persons who require it.

13. EARLY REPORTING OF MALIGNANT TUMORS

RESOLVED that the American Public Health Association endorse the principle of the early reporting of malignant tumors by physicians, hospital and diagnostic laboratories to the health department where the department is prepared to tabulate and analyze the material which would come in through these reports as an important step toward better understanding and control of cancer.

THE RECIPIENTS OF THE LASKER AWARDS FOR 1946

Individual Awards—Left to right: First row: Dr. John Friend Mahoney, Dr. Alfred Newton Richards, Dr. George Baehr; Second row: Dr. Alexander S. Wiener, Dr. Carl Ferdinand Cori, Dr. Philip Levine.

The Lasker Awards for 1946 were conferred by the American Public Health Association on November 12, 1946, at the Opening General Session of the 74th Annual Meeting in Cleveland, Ohio, upon the following individuals and for the achievement noted:

DR. CARL FERDINAND CORI—For research in the rôle of anterior pituitary, insulin and hexokinase in carbohydrate metabolism.

DR. KARL LANDSTEINER (posthumously), **DR. ALEXANDER S. WEINER** and **DR. PHILIP LEVINE**—For research in the Rh factor.

DR. JOHN F. MAHONEY—For research in the penicillin treatment of syphilis.

DR. ALFRED NEWTON RICHARDS—For organization and administration of the Committee on Medical Research of the Office of Scientific Research and Development.

DR. FRED L. SOPER—For organization of eradication campaigns against yellow fever and malaria.

The following groups were cited for the achievement noted:

THE ARMY EPIDEMIOLOGICAL BOARD—For distinguished service in the control of infectious diseases, bringing a permanent enrichment to medical science.

DR. FRANCIS G. BLAKE was the recipient of the award on behalf of the group.

Group Citations—Left to right: Dr. R. E. Dyer, Dr. G. E. Hilbert, Dr. Francis G. Blake, Dr. Fred C. Bishopp, Dr. George Baehr.

THE BOARD FOR THE COÖRDINATION OF MALARIAL STUDIES—For accomplishments leading to a rational approach to the eventual solution of the malaria problem.

THE BUREAU OF ENTOMOLOGY AND PLANT QUARANTINE—In recognition of distinguished service in the solution of problems involving the health and comfort of the Armed Forces, with particular reference to insect-borne diseases.

DR. FRED C. BISHOPP was the recip-

ient of the award on behalf of the group.

THE NATIONAL INSTITUTE OF HEALTH—In recognition of its fundamental contributions to the prevention and control of disease.

DR. R. E. DYER was the recipient of the award on behalf of the group.

THE NORTHERN REGIONAL RESEARCH LABORATORY—For studies leading to the mass production of penicillin.

DR. G. E. HILBERT was the recipient of the award on behalf of the group.

RESTATEMENT OF POLICY OF THE ENGINEERING SECTION

The Engineering Section of the American Public Health Association adopted the following statement of policy at the Annual Meeting in Cleveland, November 12, 1946:

"The Engineering Section Council proposes that the following statement of policy be adopted by the Section:

1. That the scope of activity of the Engi-

neering Section shall include all technical and professional interests in the field of environmental health.

2. That the Section Council shall coöperate with other public health engineering and sanitation groups seeking some practical medium of effort to unify and further the interests of all workers, and to that end each state or group of states in which an organization of workers in environmental health, recognized as such by the official state health agency, shall be invited to designate a representative of that group to be a member of an advisory

policy committee to the Engineering Section Council.

3. That the Section Council shall further explore the field of environmental health as a basis for such changes and modifications in Section activity as may be *desirable* to achieve its greatest usefulness in all phases of sanitation and the Section Council shall submit a report of its findings at the next annual meeting.

It further proposes that membership of the Section shall be informed regarding this action."

Through this announced policy the Engineering Section hopes to provide the needed professional representation for all categories of workers in the field of sanitation.

LT. COL. WILLIAM T. INGRAM APPOINTED ENGINEERING FIELD ASSOCIATE FOR A.P.H.A. STAFF

The Executive Board of the American Public Health Association has appointed Lt. Col. William T. Ingram, U.S.P.H.S., of Berkeley, Calif., as Engineering Field Associate.

As pointed out in the report *Local Health Units for the Nation*, by Dr. Haven Emerson and the committee, there is a need for more than 1,000 additional public health engineers to meet even minimum requirements in the field of environmental health. The need for professional leadership in this field has been recognized as a paramount problem by the Engineering Section Council and the Association's Committee on Professional Education. Consequently the Section Council with the approval of the Executive Board has undertaken a field project to explore the problems related to sanitary and public health engineering with a view toward:

1. More adequate provision of needed personnel employed in the sanitation of the environment

This statement is considered particularly timely by many members of the Section and the Association as a whole as positive action toward unification of the interested groups in the field of environmental sanitation. The decision of the Engineering Section also comes at a time when the Association is in a particularly fortunate position for contributing to the exploratory work called for by the work already undertaken by Francis B. Elder, Engineering Associate, and through his continued services and those of Lt. Colonel William T. Ingram, now on terminal leave from the U. S. Public Health Service, who has recently joined the staff of the Association as Engineering Field Associate.

2. Establishing the engineer in a position of greater usefulness to the administrator

3. Developing sanitary engineering and public health engineering as professional careers offering attractive opportunities to young men now entering our colleges and universities

4. Stimulating universities to the expansion

William T. Ingram

of undergraduate and graduate curricula which will prepare the student for his professional engineering rôle

5. Improving and broadening the environmental health services in all of the functional fields in keeping with state and community requirements

Col. Ingram brings to the Association a wide range of experience, including design, construction, surveying, stream pollution investigation and works maintenance. His public health experience includes work at local, state, national, and international levels with the San Joaquin Local Health District, State of California, U. S. Public Health Service, and United Nations Relief and Rehabilitation Administration.

Through his membership in professional associations he has developed a wide acquaintance with the sanitation field. He is a Fellow of the American Public Health Association and past

chairman of the Municipal Public Health Engineering Committee, Engineering Section; Associate Member, American Society of Civil Engineers; Member, Federation of Sewage Works Associations, and past secretary of the California Sewage Works Association; Member, American Water Works Association; Member and past chairman, Conference of Municipal Public Health Engineers. Col. Ingram is a Registered Civil Engineer in the State of California.

He received his A.B. in Civil Engineering at Stanford University and his Master of Public Health at Johns Hopkins University.

The field project has been underwritten for a period of two years by the National Foundation for Infantile Paralysis through funds from their March of Dimes, and by a group of sanitary engineering industries.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

S. E. Ferreira, M.D., D.P.H., Island Medical Officer, Kingston, Jamaica, B.W.I., Asst. Director, Medical Services, Government Medical Service
Hossein Hafezi, M.D., D.T.M., 124 Shahine Ave., Kakh, Tehran, Iran, Director, Dept. of Vital Statistics and Health Education, Ministry of Health
J. A. Haney, M.D., 428 Market St., Steubenville, Ohio, Health Commissioner, Jefferson County Health Dept.
Robert F. Hansen, M.D., M.P.H., 620 S. 3rd St., Louisville 2, Ky., Surgeon (R), U. S. Public Health Service
Robert E. Harper, M.D., 603 E. 4th St., Tusculumbia, Ala., Colbert County Health Officer
Julius G. Hart, Jr., M.D., 67 Myrtle Ave., Westport, Conn., Health Officer
Charles R. Hayman, M.D., 414 S. State St., Dover, Dela., Deputy State Health Officer
Clair A. Henderson, M.D., 23 E. Charlton, Savannah, Ga., Health Officer
G. Lilian Hutton, M.B., Okanagan Valley

Health Unit, Kelowna, B. C., Canada, Director
Joseph P. Kesler, M.D., 470 13th St., Ogden, Utah, District Health Officer
Thomas Lindsay, British Embassy, 3400 Massachusetts Ave., Washington 8, D. C., Asst. Secretary, Ministry of Health
Robert L. Loftin, M.D., Bay County Dept. of Health, Bay City, Mich., Director
Dennys L. Lyall, Government Health Inspector, P. O. Bindura, Southern Rhodesia
Athanasios G. Mandekos, M.D., M.P.H., Kyrillou Loukareos 4, Athens, Greece, Asst. Professor, Athens School of Hygiene
Paul W. McCracken, M.D., 219 East Oregon Ave., Phoenix, Ariz., Director, Maricopa County Health Unit
John R. Philp, M.D., 41 Edgewater Rd., P. O. Box 507, Nantasket Beach, Mass., Student, Harvard School of Public Health
Marjorie Rowntree, M.D., 624 East Jefferson St., Louisville, Ky., Director, East Louisville Health Center, Louisville and Jefferson County Health Dept.
Anton J. Schramel, M.D., City Hall, Room

- 613, Milwaukee, Wis., Deputy Commissioner of Health
 Cecil G. Sheps, M.D., 15 Dwight St., New Haven, Conn., Student, Yale School of Medicine, Dept. of Public Health
 Leland W. C. Sturgeon, M.D., D.P.H., 120 King St., Welland, Ont., Canada, Director and Medical Officer, Welland District Health Unit
 V. L. Van Duzen, M.D., 150 Mill, Big Rapids, Mich., Director, Mecosta-Osceola Health Unit
 Edwin S. Warrell, 14 Main St., Hingham, Mass., Exec. Health Officer, Health Dept.

Laboratory Section

- Chester W. Anderson, 2223 Grant Ave., Rockford, Ill., Laboratory Director, Rockford Health Dept.
 E. Lawrence Barton, M.D., Provincial Dept. of Health, Div. of Laboratories, Toronto 2, Ont., Canada, Director of Laboratories
 Pedro P. Chanco, Jr., M.D., 522 San Antonio St., Paco, Manila, Philippines, Malariaologist, U. S. Public Health Service
 Raymond E. Daniels, 126 Erie Rd., Columbus 2, Ohio, Chief Bacteriologist, State Dept. of Health
 Irving M. Derby, M.D., 529 Church St., Newark, N. Y., Director of Clinical Laboratory, Newark State School and Wayne County
 Marvin W. Edwards, 2738 N. Grand River, Lansing 6, Mich., Public Health Bacteriologist, State Dept. of Health
 William F. Elias, Ph.D., 6302 Morton St., Philadelphia 44, Pa., Technical Director, Penicillin Division, Wyeth, Inc.
 Andrew R. Fodor, M.S., 90-79 Sutphin Blvd., Jamaica, N. Y., Technical Supervisor, Warren Medical Laboratories
 George T. E. Lloyd, 190 St. George St., Toronto, Ont., Canada, Asst. Bacteriologist, Laboratory Division, Dept. of Health, Province of Ontario
 Donald K. Hesson, M.A., 1443 Mulford Rd., Columbus, Ohio, Chief of Water Bacteriology, Ohio Dept. of Health
 Guido Iannarelli, 507 Nancy St., Charleston, W. Va., Senior Bacteriologist, West Virginia Hygienic Laboratory
 Morris T. Jones, Ph.D., 2542 Forest Place, East St. Louis, Ill., Bacteriologist, Automatic Canteen Co. of America
 Russell P. Knerr, Swiftwater, Pa., Director, Biological Division, National Drug Co.
 Mary Jane Knisely, State Dept. of Public Health, Carbondale, Ill., Bacteriologist
 Walter E. Machala, 411 N. Classen, Britton, Okla., Serologist, State Health Dept.
 Jacques Olivier, M.D., Hospital St. Vincent

- de Paul, Sherbrooke, Que., Canada, Director of Laboratories
 Joseph J. Portley, 1119 Hillside Ave., Plainfield, N. J., Formerly Bacteriologist, Dept. of Health
 Clifford W. Price, 4803 27th Rd. South, Arlington, Va., Bacteriologist, U. S. Food and Drug Administration
 Roger D. Reid, Ph.D., 5 Park Drive, Baltimore 7, Md., Bacteriologist, Hynson, Westcott and Dunning
 Merrill L. Riehl, 380 Garden Rd., Columbus 2, Ohio, Chief Chemist, State Dept. of Health
 Walter A. Rugh, Rt. 2, Box 893A, Walnut Creek, Calif., Owner of Clinical Laboratory
 John M. Sharpley, Froehling & Robertson, Inc., P. O. Box 737, Richmond, Va., Bacteriologist and Physiological Chemist
 Dorothea M. Slater, Glenbrook Quaker Farms, Oxford, Conn., Asst. Chemist, New Haven Water Co.
 Joseph E. Smadel, M.D., Army Medical Center School, Washington 12, D. C., Scientific Director, Div. of Virus and Rickettsial Diseases
 Lorena J. Thierbach, 2510 Van Vess Ave., San Francisco 9, Calif., Bacteriologist, San Francisco Dept. of Public Health
 Juanita J. Warner, 71 Quincy St., Rochester 9, N. Y., Bacteriologist, Rochester Health Bureau Laboratories
 Dixie M. Woodburn, P. O. Box 1498, Ketchikan, Alaska, Bacteriologist, Territorial Dept. of Health

Vital Statistics Section

- Vivian B. Holland, 436 W. Wilson St., Madison, Wis., Director, Central Statistical Services Div., State Board of Health
 Elsie B. Hyatt, P. O. Box 210, Jacksonville, Fla., Administrative Asst., Bureau of Vital Statistics, State Board of Health
 H. Lukin Robinson, 200 Stewart St., Ottawa, Ont., Canada, Statistician, Dominion Bureau of Statistics
 Walter Schilling, M.D., Stanford University Hospital, San Francisco 15, Calif., Biometrist and Statistician
 Rose C. Willcox, 10402 St. Clair Ave. 211, Cleveland 8, Ohio, Principal Clerk and Deputy Registrar, Bureau of Vital Statistics, Dept. of Health
 Louise Y. Workman, 445 Beaumont Ave., Charlotte, N. C., Vital Statistician, City Health Dept.

Engineering Section

- Elton J. Braddock, 4410 45th Ave., South,

- Seattle 8, Wash., Sanitation Inspector, Seattle Health Dept.
- James G. Brown, 116 N. Michigan Ave., Hastings, Mich., Public Health Engineer, Barry County Health Dept.
- Hal F. Daniels, Box 243, Manteo, N. C., Sanitarian, State Board of Health
- Russell C. Evans, D.V.M., Health Dept., Racine, Wis., Chief, Food and Sanitation
- Frank W. Hays, Jr., 860½ 24th Ave., N., St. Petersburg, Fla., Chief of Sanitation, Pinellas County Health Dept.
- William Hogan, 150 Glenarm St., Pasadena, Calif., Owner, U. S. Termite Control Corp., Ltd.
- James G. Livingston, 104-35 102nd St., Ozone Park 16, N. Y., Health Inspector, New York City Dept. of Health
- Clarence M. Moss, Sub-Treasury Bldg., Wall-Nassau-Pine, New York 5, N. Y., S. A. Sanitarian (R), U. S. Public Health Service, District No. 1
- Leonard M. Pratt, 52 E. St. Charles Rd., Villa Park, Ill., Sanitary Engineer, DuPage County Health Dept.
- Edward L. Stockton, 218 E. Erie, Albion, Mich., Acting Engineering Director, Calhoun County Health Dept.
- Charles O. Stoy, 778 N.W. 42nd St., Miami, Fla., Dairy Sanitarian, Dade County Health Dept.
- Ralph L. Tarbett, 5 Stockton Rd., Silver Spring, Md., Public Health Engineer, Montgomery County Health Dept.
- Guy M. Tate, Jr., M.S., P. O. Box 2591, Birmingham, Ala., Director, Bureau of Sanitation, Jefferson County Board of Health
- Joseph S. Taylor, 2614 Lincoln Ave., Richmond, Va., Chemical Engineer, Bureau of Sanitary Engineering, State Dept. of Health
- Emilio Tourn, M.S., Baez 495, Montevideo, Uruguay, S.A., City Sanitary Engineer
- Harry H. Utes, 510 Court St., The Dalles, Ore., Senior Sanitarian, Wasco-Sherman-Hood River County Health Depts.
- George A. West, 5 Mile Line Rd., East Rochester, N. Y., Supervisor, Div. of Food and Sanitation, Rochester Health Bureau

Garfield Heights, Cleveland, Ohio, Exec. Director, Cleveland Hearing and Speech Center, Community Fund Agency

Aline L. Lavi, Rt. 3, Donegan Rd., Waukegan, Ill., School Nurse, Waukegan Public Schools

Dental Health Section

Demetrios M. Hadjimarkos, D.D.S., M.P.H., Oregon State College, School of Home Economics, Corvallis, Ore., Assoc. Professor
Anna Mintz, D.M.D., 416 Marlborough, Boston 15, Mass., Dentist

Oren A. Oliver, D.D.S., Medical Arts Bldg., Nashville 3, Tenn., Chairman of Public Health Council, Tennessee Dept. of Public Health

Virginia B. Winterhoff, D.D.S., 716 Hickory Lane, Benton Harbor, Mich., Public Health Dentist in Berrien County

Epidemiology Section

Robert W. Babione, M.D., Bureau of Medicine and Surgery, Navy Dept., Washington 25, D. C., Head of Sanitation and Health Branch, Preventive Medicine Division

Martin M. Cummings, M.D., 215 Bradley Ave., Mt. Vernon, N. Y., Senior Asst. Surgeon, U. S. Public Health Service

Morton H. Edelman, M.D., 1070 Park Ave., New York 28, N. Y., Parasitology, Mt. Sinai Hospital

Thaddeus M. Koppa, M.D., M.P.H., 3229 Westminister, Dallas, Tex., Formerly, Director, Bureau of Epidemiology, Michigan Dept. of Health

Richard W. Linton, Ph.D., 240 Hornby Rd., American Express Co., Bombay, India, Special Representative, Lederle Laboratories, Inc.

Aurelio Malaga, 2115 "O" St., N.W., Washington, D. C., Professor of Epidemiology, Veterinary Faculty, Lima, Peru

C. B. Stewart, M.D., M.P.H., Dalhousie Public Health Clinic, Halifax, Nova Scotia, Canada, Professor of Epidemiology, Dalhousie Univ.

School Health Section

Sidney S. Chipman, M.D., 11 Morgan Ave., Norwalk, Conn., Graduate Student, Yale University

James W. Clarke, M.D., Admin. Bldg., Parkway at 21st St., Philadelphia 3, Pa., Asst. Director, Division of Medical Services, Public Schools

Wesley P. Cushman, D.Ed., Ohio State University, Men's Gymnasium, Columbus, Ohio, Assoc. Professor of Physical Education

Egner A. Eklund, D.D.S., R.D. 1, Garrettsville, Ohio, Asst. Supervisor of Mouth Hygiene, Cleveland Board of Education

George J. Fortune, M.A., 11103 Lincoln Ave.,

Unaffiliated

Harry J. Becker, 4932 Cordell Ave., Bethesda, Washington 14, D. C., Director, Administrative Methods Unit, U. S. Children's Bureau
Ralph B. Berry, M.D., 41 Walden St., Newtonville, Mass., Student, Harvard School of Public Health

Robert H. Bishop Jr., M.D., 2065 Adelbert Rd., Cleveland, Ohio, Director, University Hospitals

George W. Brooks, 10 Cherry St., Derby, Conn., Student, Dept. of Public Health, Yale University School of Medicine

Laura B. Deane, D.M.D., 9 Central St., Lowell, Mass., Dentist

Simon D. Doff, M.D., 362 Yale Ave., New Haven, Conn., Asst. Epidemiologist, City Dept. of Health

K. Pierre Dozois, Ph.D., 1600 Arch, Philadelphia, Pa., Director, Sales Education, Wyeth, Inc.

Laurence J. East, M.S., 817 S. Park, Springfield, Ill., Administrative Assistant, State Dept. of Public Health

Stephen Fromer, M.D., M.P.H., 21 Hodges Place, Staten Island 1, N. Y., Health Officer in Training, New York City Dept. of Health

Eleanor P. Hunt, Ph.D., Children's Bureau, 14th & Constitution, N.W., Washington 25, D. C., Asst. Director, Division of Statistical Research

William C. Kenner, 4728 Schlaff Rd., Dearborn, Mich., Food and Sanitary Inspector, Dearborn Health Dept.

Elizabeth K. Lazo, M.A., 10 Audubon Place, Radburn, Fairlawn, N. J., Statistician, Merit System Unit, American Public Health Assn.

Garra L. Lester, M.D., 12 Vincent Ave., Chautauqua, N. Y., Local Health Officer

Albert M. Settles, 1357 W. 3rd Ave, Columbus, Ohio, Supervisor of Personnel, State Dept. of Health

Herman R. Shepherd, 165 Linden Ave, Bridgeport, Conn., Aerosol Research, Bridgeport Brass Co.

Frederick Swanson, M.D., 333 Sherman Ave., New Haven, Conn, Student, Yale University, Dept. of Public Health

Frank Winchell, 307 Hogan St., Jacksonville, Fla, Manager, Jacksonville Tourist & Convention Bureau

A.P.H.A. MEMBERSHIP DIRECTORY

The 1946 Membership Directory of the Association is at last a reality and every member is entitled to receive it without charge. Members who desire to receive a copy should send a post card or a letter to this effect to the Association office at 1790 Broadway, New York 19, N. Y.

population almost 50,000. Staff of 13 or more. Beginning salary \$6,600 plus \$750 travel allowance. For information, also on possible expansion with increase in responsibility and salary write Russell E. Pleune, M.D., Director, Northern Peninsula Office, Michigan Department of Health, Escanaba, Mich.

Wanted: Public health or sanitary engineer with engineering degree to direct environmental sanitation program in county health department in Southwestern Michigan. County is part of the field training area for the Michigan Department of Health. Beginning salary \$3,000 plus travel allowance. Write Box S-1, Employment Service, A.P.H.A.

Wanted: Public health nurses for staff positions in generalized public health nursing program in well established county (part of the field training area for Michigan Department of Health). Beginning salary \$2,000-\$2,400 depending on training and experience plus travel. Write Box N, Employment Service, A.P.H.A.

Wanted: Associate bacteriologist in charge of clinical laboratory in eastern state health department. B.S. degree plus three years' experience, thorough foundation in chemistry and background in bacteriology are requisites. New position with teaching duties. At present beginning salary \$3,000, annual increments, increase considered. Write Box L-3, Employment Service, A.P.H.A.

Wanted: Health Officers with experience or training in public health for County Health Units as follows: Duval County-Jacksonville; Gadsden County-Quincy; Putnam and Flagler Counties-Palatka. Also Medical Directors for Bureau of Maternal and Child Health and for Division of Industrial Hygiene, with headquarters in Jacksonville. Salaries determined by experience and training. Write State Health Officer, P. O. Box 210, Jacksonville, Fla.

Wanted: Health Educators to conduct general community health education programs at local level in Mississippi. Beginning net income \$2,400 per year with periodic increases, plus travel expenses. M.P.H. with major in health education from a recognized school required. Contact Dr. N. C. Knight, Director, Division of Health Education, State Board of Health, Jackson 113, Miss.

Wanted: State Vital Statistics Registrar. Male; \$300 to begin; Permanent. Minimum: 3 years' experience in birth and

death registrations; college graduate, preferably supplemented by one year graduate work in public health with major in vital statistics. Write or wire A. T. Johnson, Personnel Director, Oregon State Board of Health, 1022 S.W. 11th Avenue, Portland 5, Ore.

Wanted: Venereal disease control physician, St. Louis City Health Division. Special training and experience in venereal diseases; clinical, laboratory, and public health aspects required. Full-time. Civil Service. State qualifications and acceptable salary. Write Department of Personnel, City of St. Louis, Mo., 14th and Market Streets.

Wanted: Public health nursing supervisor. Should have B.S. degree, major in Public Health Nursing Supervision and minimum one year supervisory experience in generalized program. Salary \$3,000. Write Director, City-County Health Unit, 28 East Boulder, Colorado Springs, Colo.

Wanted: Medical-social worker for challenging position. Combination case work and community organization in Voluntary Health Agency, Denver, Colo. No travel. Write Box M, Employment Service, A.P.H.A.

Wanted: Qualified public health nurse with tuberculosis experience for progressive voluntary agency with active community program. West. Write Box N-2, Employment Service, A.P.H.A.

Wanted: Laboratory technician or medical secretary technician for clinical laboratory in Massachusetts. Five-and-a-half-day week, no night work. Write Box J, Employment Service, A.P.H.A.

Wanted: Medical Director for rural county, population 28,000, Midwest. Budget supplied entirely by county funds. Salary \$5,000 plus travel. One month annual vacation, pension system. Write Box Q, Employment Service, A.P.H.A.

Wanted: Staff nurse for generalized service including bedside and school nursing. Salary \$200 to \$240. City-County Health Department. Population 85,000. Seventeen staff nurses, 1 field supervisor, 1 clinic supervisor, 1 nursing director, 6 sanitarians, 1 medical director. Write Box U, Employment Service, A.P.H.A.

Wanted: Director of Nurses to supervise nurses and to direct a school for practical nurses in a new hospital. Opportunity to participate in the organization of a new hospital for the care of long-term illnesses, located at Cascade, Wash-

ington County, Maryland. Maintenance, health and retirement benefits. Proposed salary subject to approval \$3,000-\$3,750. *Requirements:* B.S. in nursing; one year's study in teaching and supervision of nursing or in hospital administration. One year in teaching and supervision of nursing in school of nursing or hospital plus one year as Director of School of Nursing; or five years as a Nursing Supervisor. Write Dr. J. A. McCallum, Cascade, Washington County, Maryland.

Wanted: Communicable Disease Control Physician with major part of work in V.D. Aptitude and interest in clinic services, and program direction preferable to experience which is desirable. Some public health training experience preferred. Fifty-bed contagious disease hospital. Beginning salary \$5,000 per year plus travel. Civil service standards. Give full qualifications first letter. Fellowships in Medical Research

Dr. Thomas Parran, Surgeon General of the U. S. Public Health Service, announces approximately 120 one year fellowships in medical research open to men and women who are graduate science students.

The National Cancer Institute, a division of the National Institute of Health, has funds to train approximately 30 physicians in the diagnosis and treatment of cancer. Doctors wishing to specialize in this field may be appointed as trainees and be assigned to authorized institutions.

The National Institute of Health offers research fellowships to graduates of accredited colleges who have majored in biology, chemistry, dentistry, entomology, medicine, physics, and other scientific fields. Senior research fellowships are awarded at a yearly stipend of \$3,000 to those who hold a Ph.D. degree in one of the specified scientific subjects. Junior

fellows receive \$2,400 annually and must hold an M.S. degree or have completed the equivalent of such a degree in post-graduate study. Fellowships may be renewed for a second year. Applications for fellowships and traineeships should be sent to the Director, National Institute of Health, Bethesda, Md.

The U. S. Public Health Service also administers fellowships for health personnel from other American republics and the Philippine Islands. Applications for these fellowships should be sent to The Surgeon General, U. S. Public Health Service, Washington 25, D. C.

Fellowships for the Training of Health Educators

The U. S. Public Health Service announces that fellowships leading to a Master's degree in Public Health in the field of health education are again being offered. Candidates must be U. S. citizens between 22 and 40 years of age, must hold a bachelor's degree from a recognized college or university, and must be able to meet the entrance requirements of the accredited school of public health of their choice.

In addition to the degree, courses in the biological sciences, sociology and education may be required. Training in public speaking, journalism, psychology, and work in public health or a related field are considered desirable qualifications.

Tuition, travel expenses for field training and a monthly stipend of \$100 will be provided out of funds furnished by the National Foundation for Infantile Paralysis. The year's training which begins with the 1947 fall term, consists of 8 or 9 months of academic work and 3 months of supervised field experience.

Veterans are encouraged to apply and will be paid the difference between the allowance under the G.I. Bill of Rights and the monthly stipend of \$100. Employees of local and state health departments are not eligible since Federal grants-in-aid are already available for such training purposes.

Application blanks may be obtained by writing the Surgeon General, United States Public Health Service, Washington 25, D. C., and must be filed prior to March 15, 1947.

Exchange of Public Health Personnel between Hawaii and the Mainland

An opportunity for public health nurses, sanitary and medical officers to work in the Hawaii Health Department

is now offered under the new exchange personnel program inaugurated by the Board of Health in the Territory.

As passed by the Hawaii legislature, the enabling act calls for an exchange of personnel for a period not to exceed a year.

Provisions in the act state that each person exchanged by the health department of any state must possess qualifications equal to the qualifications of the person exchanged for him from Hawaii and must hold in the state health department a position which is equivalent to the position held by the person exchanged for him in Hawaii.

Salaries for both exchanging parties will be paid by the home employer. Travel, board, lodging or other such expenses will not be paid by the Territorial Health Department.

Eligible persons employed on the mainland who desire to take advantage of this exchange program are requested to write Dr. Richard K. C. Lee, Assistant Health Executive of the Board of Health, Territory of Hawaii.

Openings for District Health Officers in New York City

The City of New York plans to open applications for the position of District Health Officer in January. The requirements are an M.D. degree, one year internship or residency in a general hospital approved by the American Medical Association, a Master's degree in Public Health from an institution which has such a degree registered by the State of New York, three years' satisfactory full-time experience as health officer or assistant health officer or in another administrative position in public health. The minimum salary is \$3,000, and at present four vacancies exist at \$5,750 per annum. In addition, an annual bonus of \$350 is given. Inquiries should be directed promptly to the Commissioner, Municipal Civil Service Commission, 299 Broadway, New York 7, N. Y.

U. S. Public Health Service Announces Examinations for Nurses. Examinations for the appointment of registered nurses to the U. S. Public Health Service will be given during March and April, 1947, in cities throughout the nation, according to an announcement made by Miss Lucile Petry, Chief of the Division of Nursing.

"The Public Health Service offers opportunities for recent graduates as well as experienced nurses," Miss Petry said.

"For the new registered nurse who can qualify here is an opportunity to acquire good initial experience. The Public

Health Service offers the experienced nurse a permanent career with the advantages of professionally stimulating work, job security, regular salary increases, and opportunities for advanced study and promotion on the basis of training and ability."

Nurses interested in obtaining further details concerning appointment to the U. S. Public Health Service should write to Miss Lucile Petry, Chief, Division of Nursing, U. S. Public Health Service, Washington 25, D. C. Specific dates for examinations will be announced shortly.

NEWS FROM THE FIELD

RAGWEED CONTROL

According to a recent release of the New York City Health Department, pollen counts made by the National Pollen Survey Committee in New York City during the summer of 1946 were the lowest ragweed counts since 1937. This favorable condition is attributed in part to the 6 week ragweed control program instituted through the summer of 1946. At least 3,000 acres of ragweed were treated during the campaign which utilized the facilities of many of the city's departments plus the services of Boy Scouts and other volunteer groups.

The public interest in ragweed control programs utilizing the herbicide 2,4-D, has been great, not only in New York City but also in Jersey City, N. J., and Washington, D. C., where programs were also carried on last summer. More than 100 visitors registered at the exhibit on ragweed control presented by the New York City Health Department in the scientific exhibits at the Annual Meeting of the Association in Cleveland. The paper describing similar methods for the control of poison oak and poison ivy presented by Dr. Clair E. Turner* at the Annual Meeting also evoked general interest.

To help meet the anticipated demand for information and the need for trained workers in other communities, New York University announces a special series of lectures under the title of "Control of Plants Detrimental to Health," to be sponsored jointly by the university and several of the health departments in the New York metropolitan area. The course is scheduled to start on Friday evening, March 7, 1947, at 7:30, and

will continue for at least 5 subsequent Friday evenings. An advisory group consisting of public health workers, horticulturists and representatives from New York University are preparing the curriculum and a syllabus and planning for the course in general. The faculty for the lectures will be composed of individuals who have worked in ragweed control programs.

Registration will be \$5 and will be open to employees of health departments, park commissions, mosquito control commissions, departments of public works and any other official bodies interested, as well as representatives of volunteer groups working toward the control of ragweed. Additional information can be obtained from Professor Warren Bower, Assistant to the Dean, Division of General Education, New York University, New York 3, N. Y.

WESTERN RESERVE INSTITUTE ON MEDICAL CARE AND HUMAN VALUES

Western Reserve University, Cleveland, Ohio, has announced an Institute January 16, 17, and 18 on the subject "Better Medical Care and Human Values—A Challenge to Social Workers." Faculty chairman is Professor Agnes H. Schroeder of the Medical Social Work Department, School of Applied Social Sciences. Persons admitted are required to be graduates of a school of social work or college graduates with a minimum of three years' employment in a social or health agency. Attendance is limited to 50 persons. Tuition is \$12.50. The leader of the Institute will be John Peters, M.D., Professor of Medicine, Yale University School of Medicine, New Haven, Conn., and secretary of the Committee of Physicians for the Improvement of Medical Care, Inc.

* See page 7, this issue.

RESTAURANT SANITATION ORDINANCE

The progress of the adoption of the Standard Restaurant Ordinance (or one based on it) as prepared by the U. S. Public Health Service, is described in the *News Release* dated November, 1946, of the Milk and Food Section, Sanitary Engineering Division of the U. S. Public Health Service. According to this release these ordinances are in effect in communities embracing a population of over 40,000,000. Fifteen states and the District of Columbia, plus 176 counties and 373 municipalities, have adopted such ordinances.

Copies of the suggested ordinance, *Ordinance and Code Regulating Eating and Drinking Establishments*, can be obtained from the Superintendent of Documents, Government Printing Office, Washington 25, D. C., for 20 cents each.

RED CROSS SERVICES TO VETERANS

The Motion Picture Distributing Office of the American Red Cross announces "Facing Tomorrow," a "short" motion picture designed to make known to a wide number of ex-servicemen and their families the free services available to them from their Red Cross in dealing with vital post-war problems of insurance, benefits, allotment checks, and many others. The film is available without charge, except for shipping costs. The 16 mm sound film is in two reels, running 14 minutes. Order from Motion Picture Distributing Office, American Red Cross, 40 East 49, New York 17, N. Y.

RICHARD PEARSON STRONG AWARD TO
LONDON'S DR. FAIRLEY

The fourth annual award (1947) of the Richard Pearson Strong Medal was recently made to Neil Hamilton Fairley, M.D., of the London School of Hygiene and Tropical Medicine at a special dinner of the American Foundation for Tropical Medicine. Dr. Fairley was cited as "a soldier who has conquered

disease, relieved the suffering and saved the lives of innumerable persons in many lands." During the war he was chairman of the combined Advisory Committee on Tropical Medicine to General MacArthur. As Brigadier of the Australian Army Medical Corps he directed the Medical Research Unit of the Australian Army at Cairns, Australia. This unit demonstrated the successful chemotherapeutic control of malaria in troops in the South West Pacific. Information secured on malaria and other tropical diseases, such as scrub typhus and dengue fever, "made possible an earlier termination of the war against the Japanese Empire."

The award, together with a \$500 cash honorarium, was established through a gift of the Winthrop Chemical Co. The medal is struck in white metal palladium. The presentation to Dr. Fairley was made by Colonel Strong in whose honor the award was named and who was its first winner in 1944.

AMERICAN PHARMACEUTICAL MANUFACTURERS' ASSOCIATION AWARD
TO MAYO FOUNDATION

On December 9, in New York City, the eighth annual award of distinction of the American Pharmaceutical Manufacturers' Association was made to The Mayo Foundation for Medical Education and Research "in recognition of its great contributions to public health, by fundamental research in the field of the medical sciences, for the profound and lasting benefit of mankind." This is the third consecutive year in which this award has been made to a group rather than to individual research workers.

FOUR NEW STATE DISTRICT HEALTH
OFFICERS IN MAINE

The Bureau of Health of the Maine Department of Health and Welfare announces four new district health officers secured in five months:

They are Maurice A. Priest, M.D., with headquarters in Augusta; John Kazutow, M.D., Machias; Dean Fisher, M.D., Portland; and William J. Young, M.D., Auburn.

FLORIDA PUBLIC HEALTH ASSOCIATION, INC.

New Officers Elected:

President — Frank V. Chappell, M.D., Tampa
1st Vice President—Ruth E. Mettinger, R.N., Jacksonville
2nd Vice President—Angus Laird, Tallahassee
Secretary-Treasurer—Elsie Hyatt, Jacksonville

Board of Directors, in addition to above:

Wilson T. Sowder, M.D., Jacksonville
 George A. Dame, M.D., Jacksonville
 W. H. Miller, Miami
 Robina Tillinghast, St. Petersburg
 Lorenzo L. Parks, M.D., Jacksonville
 Elizabeth Reed, Jacksonville
 B. G. Barfield, Gainesville
Representative on A.P.H.A. Governing Council—Wilson T. Sowder, M.D.

NATIONAL MALARIA SOCIETY

The National Malaria Society held its 29th annual session conjointly with the Southern Medical Association in Miami, Fla., November 4-7. During a three day session, papers setting forth the advances in the various fields of malaria were presented.

The officers for 1947 are:

President—Colonel Mark D. Hollis
President-Elect—Dr. E. Harold Hinman
Vice-President—Dr. Wendell Gingrich
Secretary-Treasurer—Dr. Martin D. Young
Directors—Dr. Justin M. Andrews, L. M. Clarkson, W. H. W. Komp

INTERNATIONAL ASSOCIATION OF MILK SANITARIANS

The International Association of Milk Sanitarians, Inc., at its Annual Meeting, October 24-27, took its first constitutional step in changing the name to International Association of Milk and Food Sanitarians, Inc. Final action will

be determined by a mail vote within the next several months.

Newly elected officers are:

President—R. G. Ross, D.V.M., Tulsa, Okla.
First Vice-President—W. D. Tiedeman, Albany, N. Y.
Second Vice-President—A. W. Fuchs, Washington, D. C.
Third Vice-President—M. R. Fisher, D.V.M., St. Louis, Mo.
Secretary-Treasurer—J. H. Shrader, Ph.D., Wollaston, Mass.

The Executive Board authorized the name of the *Journal of Milk Technology*, the official organ of the Association, to be changed to the *Journal of Milk and Food Technology*, effective with the beginning of the next volume.

CONNECTICUT LOCAL HEALTH OFFICERS BACK HEALTH DISTRICT PLAN

Connecticut health officers at their spring meeting on May 29, 1946, in Hartford voted the appointment of a committee to draft a resolution on the need of full-time departments of health for cities and towns in Connecticut, and the consideration of financial aid by the state to proposed district departments of health. At the recent official meeting of the health officers of Connecticut, held on November 20, 1946, in Bridgeport, this committee presented the following resolution which was adopted unanimously by all health officers, who filled the meeting room:

WHEREAS, The health officers of the State of Connecticut are cognizant of the limitations of a local department of health under part-time health officers such as now exist in most of the towns, boroughs and small cities and

WHEREAS, The House of Delegates of the American Medical Association, on June 10, 1942, passed a resolution urging the establishment of full-time modern health services to provide complete coverage of the nation's area and population, and

WHEREAS, The American Public Health Association at its Seventy-first Annual Meeting on October 29, 1942, resolved that all practical measures be taken by the officers and the Executive Board of the American Public

Health Association to promote the creation and adequate support of health services by local government throughout the United States to the end that no community of our people shall be left without the public care which can be best supplied only through full-time trained medical officers of health with sufficient numbers of qualified assistant personnel, be it

RESOLVED, That the health officers of the State of Connecticut urge the State legislature to take formal action on the Health District Bill which would provide financial assistance to local communities to establish full-time districts of health, and be it further

RESOLVED, That copies of this resolution be sent to the Governor and the Legislative Council of the State of Connecticut.

COLUMBIANA COUNTY, OHIO, IMPLEMENTS PUBLIC HEALTH SURVEY

A survey of public health facilities in Columbiana County, Ohio, was recently conducted by the staff of the Committee on Administrative Practice of the American Public Health Association under the direction of Roscoe P. Kandle, M.D., M.P.H., at that time Associate Field Director for the Committee.

The Columbiana County Public Health League has announced that a number of the major recommendations of the survey are now in process of attainment. The November election supported the proposal for a special levy of 8/10 mill for tuberculosis with a 78 per cent majority. In the opinion of the League, the health survey materially assisted in this attainment.

Archie W. Dalton, the Executive Secretary of the League, has announced that the general health district board is now receiving applications for a qualified health commissioner and that it is hoped shortly to announce the name of the appointee.

SEVENTEEN ILLINOIS COUNTIES VOTE COUNTY HEALTH DEPARTMENTS

Under the referendum provisions of Illinois' Searcy-Clabaugh Law, 17 counties of the state voted, at the recent election, to establish locally

financed and administered county health departments.

The favorable vote will provide these counties with full-time professional public health service as soon as the administrative units can be organized and personnel secured. This announcement was made by Dr. Roland R. Cross, Illinois State Health Officer, on November 8. Of the 17, 7 will be single county units, the remaining 10 counties will be set up in three bi-county and one four-county units. When these new counties are in operation a total of 22 counties will have full-time local health protective service covering about 1,200,000 persons.

PRENTISS AWARD TO MARY CONNOLLY

Mary Connolly, Director of Health Education, School of Public Health, University of Michigan, was presented the third annual Elizabeth S. Prentiss National Award in Health Education in Cleveland on November 12, 1946, by Dr. W. W. Peter, Chairman of the Cleveland Health Museum's National Advisory Council. The award was established in 1943 by the Museum for an individual or persons working in coöperation who have made outstanding contributions to public health education.

Miss Connolly was Director of Health Education in the Detroit Health Department for 25 years before 1943 when she joined the university staff, where, in the words of the citation, she was a "Down-to-earth" health educator, doing much by way of writing and community organization to instill an expanding knowledge of personal and community health into the minds of Detroiters.

Earlier winners of the award were Mary and Evart G. Routzahn in 1944, and Prof. C.-E. A. Winslow in 1945.

ADDITIONS TO HOSPITAL FACILITIES IN NEW YORK CITY

Plans for the expansion of two of New York City's Medical Centers were

recently announced. Both represent coöperation between municipal and voluntary agencies. The first is for the James Ewing Hospital for cancer, a city hospital for the free treatment of cancer patients. It will be a 12 story building located on grounds adjacent to both the Memorial Hospital for Cancer and Allied Diseases, a voluntary hospital, and to the Sloan-Kettering Institute for Cancer Research now under construction. Each of the three will be a unit of a projected Memorial Cancer Center. Adjacent also are the Cornell Medical College, New York Hospital Medical Center, and the Rockefeller Institute for Medical Research.

The New York University-Bellevue Medical Center plans call for a \$50,000,000 improvement program by the New York University Medical School. The buildings will include the 20 story College of Medicine and hospital, the latter designed primarily to serve patients in the modest or middle income class; a 10 story dormitory for medical students; a new university clinic; and the Institute of Forensic Medicine. Similarly, the City has announced plans to rebuild all but the newest buildings of Bellevue Hospital which now cover blocks from 26th to 30th Streets on First Avenue. The University units of the Medical Center will cover four additional blocks from 30th to 34th Street.

MEAD JOHNSON VITAMIN A FUND

The American Pediatric Society has received \$15,000 from Mead Johnson and Company, Evansville, Ind., to be known as the "Mead Johnson Vitamin A Fund." Grants-in-aid from this fund will be used for research and studies in the field of fat soluble vitamins. A committee consisting of Drs. Edward A. Park, Baltimore; Allan M. Butler, Boston, and Daniel C. Darrow, New Haven, Conn., was appointed to administer all grants-in-aid in connection

with the use of funds. All applications for grants and correspondence should be addressed to Dr. Park, 601 North Broadway, Baltimore 5.

WORK OF COMMISSION ON HOSPITAL CARE MADE A PERMANENT DEPARTMENT OF AMERICAN HOSPITAL ASSOCIATION

The American Hospital Association has announced the establishment of a department within the Association to continue certain functions previously carried on by the Commission on Hospital Care which disbanded on October 1, 1946. The Association will continue to code and tabulate hospital schedules for state survey commissions and will assist states with advice and exchange of information on developing satisfactory study methods. Maurice J. Norby, Director of Research of the Commission on Hospital Care, has been appointed Assistant Director of the Association in charge of this new activity. He will be assisted by Ronald B. Almack as research analyst and by U. S. Public Health Service personnel. Dr. David B. Wilson of the Service will act as liaison officer between the Association and the Service.

This new department is made possible by grants of \$10,000 a year for two years each by the W. K. Kellogg Foundation and the National Foundation for Infantile Paralysis. The Commonwealth Fund will publish the report of the Commission on Hospital Care. It is scheduled for 1947.

YUGOSLAV VISITORS IN UNITED STATES

Among visitors from abroad who attended the Annual meeting of the American Public Health Association at Cleveland were four men from Yugoslavia, three physicians and a sanitary engineer, who are now in the United States travelling and studying under the sponsorship of the United Yugoslav Relief Fund of America. They will be

in this country for a period of four months, observing American public health methods and administrative programs, and studying nursing and medical education and research.

To date they have visited medical and nursing schools in eastern universities, research institutions and hospitals, and are now at the University of Michigan, living at the English Language Institute, while working at the School of Public Health and having conferences in the medical and nursing schools.

The positions that these men held abroad are of interest: Dr. Radivoje Berovic is chairman of the Department of International Medicine at the University of Belgrade Medical Faculty. He is also chairman of the Committee on Medical Education for all of Yugoslavia. (This committee is a subcommittee of the Central Commission for Public Health in Yugoslavia, which corresponds to the USPHS.)

Dr. Alexander Rotovic is assistant professor in the Institute of Physiology and Physical Therapy Clinic at the University of Belgrade. Dr. Rotovic has had wide experience in research work in Czechoslovakia, Hungary, and in his own country.

Dr. Ksenofon Sahovic is head professor of the Medical Faculty of the University of Belgrade, Director of the university's Pathological Institute, and Chairman of the Clinic for Cancer and Degenerative Diseases at the university. He is a member of many learned societies in Europe.

Mr. Bogdan Teodorovic is a graduate of the School of Engineering of the University of Zagreb, and received the degree of Engineer of Architecture in 1926. In 1927 he was appointed to the Hygiene Institute of Zagreb in the Department of Sanitary Engineering. In 1929 and 1930 he was in the United States on a fellowship grant from the Rockefeller Foundation, studying with Professors Drinker and Fair at Harvard

University. At present Mr. Teodorovic is one of the outstanding sanitary engineers of Yugoslavia, and is serving in the Ministry of Health for the State of Croatia, with offices in Zagreb.

SOUTHERN BRANCH, A.P.H.A., ANNOUNCES NEW MEETING PLANS

The Southern Branch of the American Public Health Association, organized in 1932, held a meeting in Miami early in November in connection with the Annual Meeting of the Southern Medical Association. The new officers include:

President—John W. Williams, M.D., Jefferson City, Mo.

Secretary-Treasurer—John M. Whitney, M.D., New Orleans, La.

Representative to the Governing Council A.P.H.A.—Felix J. Underwood, M.D., Jackson, Miss.

At this meeting, the Southern Branch of the A.P.H.A. voted to adopt a plan to hold meetings hereafter separate from the meetings of the Southern Medical Association and at a time which will not conflict with other meetings of similar interest. Dr. Whitney has announced that definite plans are being formulated for a spring meeting of the Branch at a time and place shortly to be announced.

UNITED STATES ARMY OPENS REHABILITATION CENTER FOR HARD OF HEARING

"News Notes" for October 15, 1946. Office of the Surgeon General, U. S. Army, reports the opening of a new service at Walter Reed General Hospital. This service consists of a new center for the rehabilitation of the deafened and hard of hearing. The Aural Rehabilitation Center, as it is called, is designed to receive military personnel, as "students," those who have finished with normal treatment and surgery but who require rehabilitative attention. Major Henry C. Barnaby

will be the director. When filled to capacity there will be 250 under treatment.

PERSONALS

Central States

GLENN H. BAIRD, M.D.,† formerly of U. S. Public Health Service, has been appointed Director of Venereal Disease Control for the Kansas State Board of Health. He succeeds REGNAR M. SORENSON, M.D.,* who was lent to Kansas during the war by the Public Health Service.

LEROY L. FATHERREE, M.D.,* has been appointed new full-time Health Director of the reorganized Omaha, Neb., Department of Health. Other new appointments for this department include: B. A. BAKER, Sanitary Engineer, and LEETA A. HOLDREGE,† Director of Nurses.

J. BRENNAN GISCLARD† has resigned from the position of the Bureau of Industrial Health, Michigan Department of Health, to accept a similar position with the Detroit Department of Health.

HAROLD C. HAYNIE, M.D., recently re-

leased from military service, has been appointed Assistant Medical Director of the Ohio State University Hospital and its out-patient department, and as Assistant Professor of Medicine and Hospital Administration in the Medical School.

WILLIAM C. KEETTEL, JR., has been appointed Assistant Professor of Obstetrics and Gynecology at the State University of Iowa College of Medicine, Iowa City. JOHN W. DULIN, M.D., who resigned as Professor of General Surgery at the State University of Iowa College of Medicine, July 1, will rejoin the college of medicine faculty as Clinical Professor of Surgery at the University Hospital.

LAURENCE T. ROGERS, PH.D.,† formerly Assistant Secretary, Health Division of the Council of Social Agencies, Chicago, Ill., has joined the University of Oklahoma faculty at Norman as Professor of Health Education.

SIGSBEE R. SELJESKOG, M.D., has been appointed Superintendent of the Elizabeth Kenny Institute, Minneapolis, Minn., succeeding FRANCIS E. HARRINGTON, M.D.†

MILTON L. SHURR has been named Director of Public Health Education and Coördination for Tulsa County, Oklahoma, a newly created position with the Tulsa City Health Department. Mr. Shurr has recently been Health Consultant in Omaha, Neb.

RICHARD H. YOUNG, M.D., formerly Associate Professor of Medicine and recently Director of the Student Health Service of Northwestern University Medical School, Chicago, Ill., has been appointed Dean of the University of Utah School of Medicine, Salt Lake City. HYRUM L. MARSHAL, M.D.,† who has been Acting Dean, will now be enabled to devote full time to his position as Professor of Public Health and Preventive Medicine and Director of the Student Health Service.

* Fellow, A.P.H.A.

† Member, A.P.H.A.

Eastern States

MERL G. COLVIN, M.D.,[†] Medical Director of Lycoming County, Pennsylvania, for the past 7 years, has been appointed a member of the State Advisory Health Board.

WILLIAM L. COOK, JR., M.D., has been appointed Assistant Director of the Department of Industrial Hygiene, University of Pittsburgh, Pittsburgh, Pa. Dr. Cook was Assistant Director and later Director of the Occupational Health Division, Office of the Surgeon General, U. S. Army, during World War II.

JOHN FERRELL, M.D.,* recently Associated with the John and Mary Markle Foundation, New York, has been appointed Adviser and Consultant Executive Secretary of the North Carolina Medical Care Commission. CLEMENT C. CLAY, M.D., resigned as Executive Secretary, several months ago.

FRANKLIN M. FOOTE, M.D.,* has been appointed Medical Director of the National Society for the Prevention of Blindness, Inc., New York, N. Y. Recently discharged from the Medical Corps of the U. S. Army, with the rank of Major, Dr. Foote retains his post as Assistant Professor of Public Health and Preventive Medicine at Cornell University Medical College. He was formerly associated with the New York City Health Department and the Connecticut State Department of Health. He is the present Chairman of the Committee on Scientific Exhibits for the American Public Health Association.

JOSEPH G. HOFFMAN, Ph.D., physicist, has been named Director of Cancer Research at the Rockwell Park Memorial Institute, Buffalo, N. Y.

RALPH HORTON, M.D.,[†] has been appointed General Director of the

Tuberculosis Hospitals in the New York State Department of Health. Dr. Horton, who is now Director of the Homer Folks State Tuberculosis Hospital at Oneonta, will be responsible for inspection and supervision of all county and city hospitals which will take part in the state-wide program to eliminate tuberculosis in the state within 20 years.

ALFRED C. LABOCCETTA, M.D., has been appointed Superintendent and Medical Director of the Philadelphia Hospital for Contagious Diseases.

MORTON L. LEVIN, M.D., Director of Cancer Control, New York State Department of Health, was elected President of the Public Health Cancer Association at its annual meeting in Cleveland. He succeeds HERBERT L. LOMBARD, M.D.,* Director of the Division of Cancer and other Chronic Diseases, Massachusetts Department of Public Health.

CHALMER J. LONGSTREET, M.D.,[†] was recently honored with a dinner to mark his retirement after nearly 30 years' service as Health Officer of Binghamton, N. Y.

MARY BLANCHE MOSS has been appointed Medical Social Worker on the staff of the National Society for the Prevention of Blindness, Inc., New York, N. Y. Miss Moss's experience includes supervisory service in the Medical Social Service departments of Charity Hospital, New Orleans, and New Haven Hospital, as well as five years with the Red Cross overseas as supervisor of Medical Social Workers in the European Theatre.

HUGO MUENCH, M.D.,* a former staff member of the International Health Division of the Rockefeller Foundation, and Professor of Biostatistics in Harvard University's School of Public Health, has been appointed head of the Department of Biostatistics. Dr. Muench is also Assistant Dean.

* Fellow, A.P.H.A.

† Member, A.P.H.A.

CHANGES IN NEW YORK STATE DEPARTMENT OF HEALTH:

JOHN K. MILLER, M.D.,† Albany, N. Y., has been appointed Associate Director of the Division of Laboratories and Research, succeeding MARY B. KIRKBRIDE, D.Sc.,* who retired July 1. Dr. Miller has been associated with the Department since 1937, and since 1942 has served with the Army, most recently in the Mediterranean Theatre as Colonel in the Medical Corps.

J. C. BOLAND, M.D.,† recently Health Officer of the City of Troy, N. Y., has been appointed Deputy County Health Commissioner of the newly organized Rensselaer County Department of Health, which includes the City of Troy.

FRANK E. COUGHLIN, M.D., DR.P.H.,* formerly New York State Department of Health District State Health Officer, has been appointed County Commissioner of Health in the Rensselaer County Department of Health, Troy, N. Y., effective November 1, 1946.

THEODORE S. DRACHMAN, M.D.,† Assistant District Health Officer, who has been on military leave since June, 1943, has resigned from the department and was appointed to the position of Deputy Commissioner of Health of Westchester County, effective August 13, 1946.

GEORGE JAMES, M.D.,* formerly Assistant District Health Officer in the Middletown district, has been appointed to the position of District Health Officer and assigned to the Kingston district to replace BERWYN F. MATTISON, M.D.†

EUGENE B. WILSON, M.D., who has been serving in the armed forces for the past two years, has been reinstated as Assistant Director of the Medical Rehabilitation Bureau.

A. J. CANNING, M.D., formerly of Rhoads General Hospital, Utica, was appointed as Director of the New York State Reconstruction Home at West Haverstraw, effective September 1, 1946. KENNETH S. LANDAUER, M.D., who has served as Acting Director since the retirement of the former superintendent, has resigned from the department to accept appointment as Director of Medical Care of the National Foundation for Infantile Paralysis. He will continue to serve as consultant to the New York State Reconstruction Home.

JERAULD A. CAMPBELL, M.D.,† formerly County Health Officer of the Mason-Bracken Health Department, Maysville, Ky., has been appointed Assistant District Health Officer of the Rochester district, effective November 16.

HARRY L. CHANT,* district State Health Officer in Middletown district, has resigned to accept an appointment as Associate Professor in the Department of Public Health, School of Hygiene and Public Health, Johns Hopkins University, and Director of the Eastern Health District, Baltimore City Health Department.

DOUGLAS POTEAT, former Vice-President of the American Red Cross, has been appointed Administrative Head of the American Cancer Society, New York, N. Y.

OTTO R. POZDENA, M.D., of Woodside, N. Y., has been appointed Acting Registrar and Director of the Bureau of Records, New York City Department of Health.

ELMER H. STOTZ, PH.D., has been appointed Professor of Biochemistry and Chairman of the Department of Biochemistry, University of Rochester School of Medicine and Dentistry, Rochester, N. Y. He will succeed WALTER R. BLOOR, PH.D.

Southern States

CHANGES IN HEALTH PERSONNEL IN ALABAMA:

JAMES L. CARPENTER, M.D., of Huntsville, has been appointed Health Commissioner of Madison County.

CLAUDE D. KILLIAN, M.D., of Fort Payne, has resigned as Acting Health Officer of DeKalb County.

GUSTAVE J. DAMMIN, M.D.,† has been appointed Assistant Professor of Internal Medicine and Assistant Professor of Pathology, Washington School of Medicine, St. Louis, Mo. He will serve as Director of the Central Diagnostic Laboratories at Barnes Hospital, St. Louis, and will aid in the teaching of laboratory diagnosis in the Department of Medicine. Dr. DAMMIN has recently been released from military services where he has been in charge of the Laboratory Division in the Office of the Surgeon General.

EVERETT H. ELLINWOOD, M.D.,* of Raleigh, N. C., has been named Health Officer for the Catawba-Lincoln, N. C., District Health Department succeeding HAROLD C. WHIMS, M.D.,† who holds a similar position in Buncombe County, N. C.

CORNELIUS W. KRUSE, M.S. (sanitary engineering) has been appointed Associate Professor of Sanitary Engineering at the Johns Hopkins School of Hygiene and Public Health, Baltimore, Md.

CHANGES IN HEALTH PERSONNEL IN MARYLAND:

NELS A. NELSON, M.D.,* Assistant Professor of Venereal Diseases at the Johns Hopkins University School of Hygiene and Public

Health, Baltimore, has been appointed Director of the Bureau of Venereal Diseases in the Baltimore City Health Department.

HENRY F. BUETTNER, M.D.,† has been named Acting Director of the Bureau of Social Hygiene in the Baltimore City Health Department succeeding HUMPHREY WARREN BUCKLER, M.D.

THOMAS B. TURNER, M.D.,* Professor of Bacteriology, Johns Hopkins School of Hygiene and Public Health, and ALLEN F. VOSHELL, M.D., Professor of Orthopedic Surgery, University of Maryland School of Medicine and College of Physicians and Surgeons, have been appointed Consultants to the Baltimore Department of Health.

ROBB S. SPRAY, PH.D., has retired as Professor of Bacteriology at the West Virginia University School of Medicine, Morgantown, where he has been a member of the faculty for twenty-five years. He has been named Professor Emeritus. JOHN M. SLACK, PH.D., who has been in the Sanitary Corps of the U. S. Army for the past 4 years, has been named to fill the vacancy.

FRED WAMPLER, M.D.,* of Richmond, Va., has been named Director of the Page-Warren-Shenandoah Health District, Virginia State Department of Health, effective September 1.

GIDEON D. WILLIAMS, M.D., has been appointed Director of the Ouachita Parish Health Center, Monroe, La. He has been serving in a similar capacity with the East Baton Rouge Parish Health Center.

JOHN B. YOUNG, M.D., has been appointed Dean of the University of Illinois College of Medicine, Chicago. He has been Professor of Medicine at Vanderbilt University School of Medicine, Nashville, Tenn.

* Fellow, A.P.H.A.
† Member, A.P.H.A.

Western States

JOHN W. BROWN, M.D., Director of Clinical Laboratories, University of California Hospital, and Assistant Professor of Medicine, University of California Medical School, San Francisco, has been appointed Professor of Preventive Medicine and Director of the Department of Student Health at the University of Wisconsin Medical School, Madison. Dr. Brown will utilize the Student Health Service as a demonstration unit for closer correlation of clinical practices with preventive medicine in the broader field of public health.

CHANGES IN HEALTH PERSONNEL IN CALIFORNIA:

KENNETH W. HAWORTH, M.D., formerly of Pratt, Kan., has been appointed Health Officer for Humboldt County.

EVELYN F. BUCHHEIM, M.D.,† for the past 2 years district Medical Officer for the Fresno area, California Department of Public Health, has resigned.

HAROLD T. CASTBERG, M.D.,* has resigned as Chief of the Bureau of Adult Health to become Director of Field Investigations for the U. S. Public Health Service, Industrial Hygiene Division, Bethesda, Md.

LESTER BRESLOW, M.D.,† is Acting Chief of the Bureau of Adult Health.

MARY B. DALE, M.D.,† has been appointed Epidemiologist for the Los Angeles, Calif., County Health Department. Newspapers report that she is the first woman to hold such a position in the county.

ALFRED ROE MASTEN, M.D., has been appointed Director of the Tuberculosis Control Section of the Oregon State Board of Health. Dr. Masten

has been Director of Tuberculosis Control for the Colorado State Board of Health, Denver.

FRANK B. QUEEN, M.D., has been appointed Professor of Pathology at the University of Oregon Medical School, Portland, Ore., and Director of the State Cancer Control Program. As Director of the Cancer Program he will serve under the joint auspices of the Medical School and the Oregon Division of the American Cancer Society.

PHINEAS J. SPARER, M.D.,† who recently joined the staff of the Jewish Consumptives' Relief Society as Medical Director has been named Superintendent of that Sanatorium in Denver, Colo. Dr. Sparer came to the Sanatorium from the U. S. Army after 3 years with the Tuberculosis Service at Fitzsimons General Hospital, Denver, Colo.

Puerto Rico

JUAN A. PONS, M.D., Puerto Rican physician, has been appointed Commissioner of Health of Puerto Rico to succeed ANTONIO FERNÓS-ISERN, M.D.,* now resident commissioner of Puerto Rico in Washington, D. C.

Foreign

DAGMAR JOHNSON, R.N.,† nursing representative with American National Red Cross Civilian Relief, has returned from Europe and joined the National Red Cross nursing staff in this country. Miss Johnson served with the Public Health Section of the Allied Military Government in Germany, working with displaced persons. Going from Germany to Holland, Miss Johnson worked in coöperation with the Medical Section of the Dutch Red Cross in hospital and public health activities. She later moved on to the Scandinavian countries, where she worked

Completely Revised Edition

The Money Value of A Man

By

LOUIS I. DUBLIN, Ph.D.

Second Vice President and Statistician; and

ALFRED J. LOTKA, D.Sc.

Assistant Statistician, Metropolitan Life Insurance Company

THIS BOOK has long been accepted as a standard guide for determining the money values of persons at various ages according to their earnings. In this newly revised edition extensive recomputations have been made in the tables to conform to altered conditions, resulting largely from lowered interest rates and increased expectancy of life. Also, the structure of the final tables showing the money value of a man by age and income has been remodeled, with definite advantage to the user.

It will be of specific value not only to health officers and social workers interested in the costliness of disease and premature death, but also to insurance officers and agents, lawyers, jurists, statisticians and economists.

OUTLINE OF CONTENTS

Historical Retrospect. The American Family. Cost of Bringing Up a Child. Income in Relation to Age and Economic Status. Money Value of a Man as a Wage Earner. Burden of the Handicapped. Valuation of Indemnity for Personal Injury or Death.

Disease and the Depreciation of the Money Value of a Man. Application to Public Health. Application to Life Insurance. Social Insurance in Relation to the Money Value of a Man. Age Schedules of Family Consumption Units and Savings. Effect, Upon Money Values, of Changes in Basic Data. *Tables and Charts.*

Price \$6.00

Brucellosis in the United States*

ALICE C. EVANS

National Institute of Health, Bethesda, Md.

THE ORIGINS OF BRUCELLOSIS IN THE UNITED STATES

The earliest human cases—In 1906 the first report of a case of brucellosis contracted in this country was published by Craig. Having seen other cases in this country among soldiers who had become infected in the Philippines, he recognized the disease in a nurse who, it was believed, had contracted the infection in Washington, D. C. Because at that time the belief prevailed that brucellosis did not exist in temperate climates, it was supposed that the patient must have contracted the infection while carrying on her work of caring for returned soldiers in hospitals. That explanation is hardly satisfactory now, for we know the unlikelihood of transmission of the disease from person to person. Furthermore, the nurse had never taken care of a recognized case of brucellosis.

In 1911 Ferenbaugh, and Gentry and Ferenbaugh reported 12 cases of brucellosis which they had seen that year in the goat-raising section of southwestern

Texas. Ten of the patients were goatherds or ranchmen who worked with goats and lived in houses surrounded by them; two were boys who had often played in dusty goat-pens. Some of the patients had never drunk goat's milk.

On inquiry the investigators learned that similar cases had occurred in that locality for a long time, and that it was known among the people by various names, such as "goat fever" and "dust fever." The doctors of the region had realized that in many respects the fever was different from typhoid. In 1894 there had been an outbreak of 25 cases in one locality, occurring almost entirely in families that had goat-pens closely surrounding their houses.

In 1923 Holt and Reynolds studied the serologic evidence of brucellar infection of goats in the Southwest. From local laymen they learned of a human disease which was apparently brucellosis. Their inquiries led them to believe that it must have existed in that locality for at least 40 years.

According to Gentry and Ferenbaugh (1911) the goats of Texas are descended from goats imported from four countries—Spain, Malta, Asia Minor, and South

* Special Review Article prepared at the request of the Editorial Board. Read before the First Inter-American Congress for Brucellosis, in Mexico, D. F., October 28, 1946.

Africa. That brucellosis is prevalent in the goats of the Mediterranean countries is common knowledge, and Gentry and Ferenbaugh quote South African investigators who proved that the disease existed in that country. Hence it may be assumed that the date of the first arrival of goats in Texas was followed shortly by cases of human brucellosis.

The first appearance of the disease in cattle—Brucellosis is known to have existed in the cattle of this country for more than a century. It is the subject of repeated discussion in the tenth volume of *The Cultivator*, published in Albany, N. Y., in 1843, edited by Gaylord and Taylor. At that early date many losses due to this bovine disease were reported from New York, Pennsylvania, Delaware, and Virginia.

Brucellosis may have been brought to this country in cattle very early, for according to Edwards (1921) it existed in the cattle of Great Britain before the settlement of the American Colonies. This author quotes Mascal, who wrote in 1567 that in some parts of Great Britain 50 to 60 per cent of the cows were "slipping" their calves.

The extent to which the bovine disease was transmitted to man prior to its recognition during recent decades can never be known. If the human disease were always as widely prevalent as it is today, it seems as if its derivation from cattle would have been suspected. It may be that the bovine strains of earlier times were of comparatively mild virulence for man, and that human infection occurred only rarely. The records of brucellar strains spreading through animal species which hitherto had been unaffected, as presented in the following pages, permits the supposition that man may have been relatively insusceptible to the strains of brucella which infected the cattle of this country a century ago.

However, Hardy, *et al.* (1930) were

convinced that brucellosis was the protracted fever which was described during the latter part of the 19th century by a number of authors. Caulkins (1878), a doctor in rural Southeastern Michigan, wrote that a mild type of fever which differed from typhoid fever and malaria was first noted in certain sections of the country about 1861. He reported cases in which the symptoms were typical of acute brucellosis.

The first appearance of the disease in swine—Unlike the histories of brucellosis in goats and cattle, the history of the disease in the swine of this country is definite, for it began somewhat more than 30 years ago. In 1914 Traum published the statement that reports of the farrowing of hairless and immature pigs had been received by the United States Department of Agriculture from several of the western and middlewestern states. From the liver and other organs of a hairless pig received from Indiana, he obtained a culture which resembled the organism of contagious abortion of cattle. Two years later Good and Smith reported their study of the porcine disease and its causal agent in Kentucky. They stated that only three outbreaks had come to their attention. In 1920 Hayes and Traum reported that infectious abortion was becoming increasingly prevalent in the sows of California. They estimated that it might be present in 9 per cent of the herds of that state. In 1930 Hardy, *et al.* reported that of the 611 hogs which they examined in Iowa, 18 per cent gave serological evidence, and an additional 16 per cent gave doubtful evidence of infection. In the preceding year Theobald Smith reported that he had obtained cultures of the organism of contagious abortion from porcine fetuses in an outbreak which he believed was the first reported in the eastern part of the United States. According to Stone (1943) the hogs of New York State were free of brucellosis until 1941.

INVESTIGATIONS

When the scene of brucellar investigations shifted from European countries to the United States, about 1910, it was known that the human disease, called undulant, Malta, or Mediterranean fever, is prevalent in Mediterranean countries; that it is contracted by means of contact with infected goats, which, even when apparently in good health, excrete the causal organism, *Micrococcus melitensis*, in the milk and urine. From Mediterranean countries the disease was known to have spread to other subtropical regions, carried by exported goats.

Another fact known at that time, but entirely disconnected with the knowledge about "undulant fever" was that contagious abortion of cattle is due to an infection of the cow with an organism designated *Bacillus abortus*, which was discovered in 1897 by a Danish veterinarian named Bang.

The first publication to appear in this country on the causal organism of brucellosis in domestic animals was a confirmation of Bang's observation, by MacNeal and Kerr, in 1910. In the following year an important discovery was made by investigators of the Bureau of Animal Industry, United States Department of Agriculture. Schroeder and Cotton reported that they found the organism of contagious abortion in milk derived from apparently healthy cows. In that same year, Mohler and Traum examined the tonsils removed from 56 children, and succeeded in isolating the organism of contagious abortion from one. In commenting on these discoveries, Dr. Melvin, Chief of the Bureau of Animal Industry, made a prophetic statement: "The fact that this organism was found in 8 samples of market milk among 77 samples tested (over 11 per cent) and in the milk distributed by 6 among 31 dairies (over 19 per cent) leaves no doubt that we are dealing with a phenomenon that is

ominously serious in its significance for public health."

Into the Dairy Division* of the Bureau of Animal Industry the writer came, and was assigned the task of studying the bacteria which occur in freshly drawn milk, that is, the bacteria which grow within the cow's udder and are excreted in the milk. Because the pathologists of the Bureau were deeply involved in investigations of Bang's disease, it was quite natural that the Gram-negative organisms which the Chief had "viewed with alarm" should become the object of keen interest to the dairy bacteriologist. Discussions with the pathologists were frequent and searching. One day in 1917 in a conversation with Dr. Adolph Eichhorn the idea evolved that it might be worth while to compare Bang's "*Bacillus abortus*" with the so-called "*Micrococcus melitensis*." It was the fact that both organisms were known to be excreted in the milk of apparently healthy animals that suggested their comparison.

Whose idea was it? It was one that neither the bacteriologist nor the pathologist could have formulated in solitary cogitation at that time. It developed when two minds, viewing the subject from different angles, were reciprocally stimulated in the search for facts bearing on related problems.

Immediately the bacteriologist set up simple experiments to test the idea, and with amazement noted that one result after another pointed to a close relationship between the strains of supposedly different genera. They were alike in morphology, in staining reactions, and in biochemical reactions. They were alike culturally, except that the strains of caprine and human origins produced a brownish discoloration of the medium after long incubation. They appeared alike when tested in an anti-

* Now designated the Bureau of Dairy Industry.

serum produced by a strain of bovine origin, for this serum agglutinated strains of bovine and human origin in equal titer. An antiserum produced by a strain of human origin also agglutinated antigens of both types, but the titer was somewhat higher when tested with antigen prepared with a strain of human or caprine origin. Pregnant guinea pigs inoculated with a strain of human origin aborted with the same degree of promptness as did those inoculated with a strain of bovine origin. Of all the tests applied at that time, that of agglutinin-absorption was the only one which could distinguish the strains of different origin.

As the older bacteriologists will remember, these findings, which were reported at the annual meeting of the Society of American Bacteriologists, held in Washington, D. C., in December, 1917, encountered skepticism when they were published in July, 1918. The only reason which the writer ever heard given to account for their tardy acceptance was that if there was a close relationship between the two supposed genera, other bacteriologists would have noted it. Although the accuracy of some of the statements in question could have been confirmed in a few hours, one distinguished bacteriologist continued for seven years to deplore the confusion caused by what he considered hasty publication. Even the writer's colleagues, the pathologists of the Bureau of Animal Industry, did not believe that the results could have been accurate. This statement was confirmed recently by one of them* who at the time was one of the younger members of the staff.

The skepticism ought to have been dispelled earlier than it was, because the original observation of a close relationship between the organisms of bovine

contagious abortion and human "undulant fever" was confirmed by Meyer and Shaw in 1920, and by 10 other investigators in 7 foreign countries within the next four years. (This literature was reviewed by the writer in an earlier publication [1925].)

The close relationship between the two organisms raised a question as to why no cases of disease were ever traced to cattle. There was no satisfactory answer for a number of years. We could only ask: "Are we sure that cases of glandular disease, or cases of abortion, or possibly diseases of the respiratory tract may not sometimes occur among human subjects in this country as a result of drinking raw cow's milk?" (Evans, 1918.)

Human cases of proved brucellar infection—The beginning of an answer came in the fall of 1922, when a culture was received from Dr. Harold L. Amoss of the Johns Hopkins Hospital. It had been isolated from the blood of a patient with the symptoms of undulant fever who denied having had any association with goats or their products. The culture came with the request that it be studied to determine whether it was *Micrococcus melitensis* or *Bacillus abortus*. According to the agglutinin-absorption test, the culture was unquestionably not of the caprine type.

This case, which was reported by Keefer (1924) was the first to be reported in medical annals in which brucella not of caprine origin were proved to be the cause of human disease. Later information revealed that the patient had contracted the disease from tissues obtained from a slaughter house. As an assistant in the histological laboratory of Johns Hopkins Medical School, he went frequently to a slaughter house to obtain tissues for purposes of teaching. Subsequent studies showed that his infection was with the porcine type of the organism, and that the mode of his infection, which resulted

* Dr. Harry Schoenig, in a discussion at a meeting of the Bacteriological Seminar, University of Maryland, June 7, 1945

from the handling of infected hogs or their carcasses, is typical of a large percentage of cases occurring in this country.

The finding of one human case of brucellosis due to the organism of contagious abortion stimulated a prompt search for others. The writer collected the remnants of samples of serum obtained routinely in Washington hospitals for the Wassermann test, and tested them for brucellar agglutinins. Among 500 samples, one serum gave a strongly positive reaction, and two gave positive reactions in the dilution of 1 to 40 (Evans, 1924). At that time we did not know how to interpret such a low reaction. We know now that it may be suggestive of infection (Evans, Robinson, and Baumgartner, 1938). In the case of the strongly positive reaction, the doctor in charge made a diagnosis of brucellosis, for the history and symptoms agreed with that disease. The patient, who lived in Clarendon, Va., stated that he drank raw cow's milk habitually, but that he had never consumed goat's milk or any of its products. Agglutinin-absorption tests made on his blood serum indicated that the infection was of the bovine type. This second case of brucellosis caused by the organism of contagious abortion was recognized in March, 1923. The clinical history of this case was not reported, but the laboratory findings were reported (Evans, 1924).

Keefer's report of the first recognized case of brucellosis in this country not of caprine origin is frequently mentioned in the literature. The order of sequence of the third, fourth, and fifth cases is established by the dates on which cultures were sent to the writer for identification, and it is confirmed by the dates given in the published reports. The dates of publication of the reports follow one another in a different order.

The third case was reported by Gage and Gregory (1926). A culture ob-

tained from the blood was received in May, 1924. Agglutinin-absorption tests showed that it was not of caprine origin. The patient, whose job was the killing of hogs, had worked for five years in a slaughterhouse in Sioux Falls, S. D.

Also the history of the fourth case, which was reported by Knowlton (1925) indicated that the infection was contracted from hogs in a slaughterhouse. A blood culture was received by the writer in August, 1924. Agglutinin-absorption tests showed that it was not of caprine origin.

A blood culture from the fifth case, which was reported by Carpenter and Merriam (1926) was received in February, 1925. Agglutinin-absorption tests showed that it was not of caprine origin. In this case, which occurred in Ithaca, N. Y., the history pointed to cow's milk as the source of the infection.

Human cases are recognized in South Africa also—Almost simultaneous with these events in this country was the recognition of brucellosis in South Africa in cases in which goats could not be implicated. According to the veterinarian, Bevan (1933), after he had read, in 1921, of the relationship between the causal organisms of Bang's disease and undulant fever, it occurred to him that certain hospitalized patients of his acquaintance might be infected with the bovine type of the organism. The results of agglutinative reactions strengthened that supposition, and in November, 1921, he reported at a meeting of the Southern Rhodesian Veterinary Association that he had tested the blood of a patient, and obtained a rapid and marked agglutination with Bang's organism in dilutions as high as 1:200. This seems to have been the first reported observation anywhere in the world of evidence of human infection with Bang's organism. The report was published in January, 1922. It mentions other human cases which were detected in a certain district "within the

last few months." In 1924 Bevan wrote that cases similar to the one mentioned in his earlier publication continued to occur. In 1925 he wrote that 35 cases of undulant fever had been recognized in persons in Southern Rhodesia who could not have been infected from goats. At that time only 5 such cases had been recognized in the United States.

Working in the same area with Bevan was the bacteriologist Orpen. In 1923 he described the method by which he obtained brucella from Rhodesian patients with undulant fever. By agglutinin-absorption tests he identified these strains with the bovine type of the organism (1924). Orpen does not give the date when he first obtained cultures of brucella from patients. Hence it cannot be stated whether this proof of human infection of bovine origin antedated the cultivation of brucella from the Baltimore case.

Many cases of brucellosis are found— Following these observations an occasional human case of brucellosis of other than caprine origin was recognized here and there in the United States and in other parts of the world. Usually the recognition of one case aroused interest, which resulted in finding other cases in the neighborhood. In April, 1925, an editorial appeared in the *Journal of the American Medical Association* calling the attention of physicians to the existence of brucellosis in parts of the United States where it was hitherto unsuspected. Probably as a result of this editorial, recognition of cases became more frequent. By the end of 1926, data were available on 20 cases from which a sample of serum and/or a culture was sent to the writer for study. These were examined by means of the agglutinin absorption test, and the result indicated the type of infection. A report of the findings was published in the *Journal of the American Medical Association* in February, 1927.

Then the number of recognized cases

began to multiply by leaps and bounds. In 1927, 217 cases were reported in *Public Health Reports*; in 1928, 649 cases; in 1929, 1,301 cases; in 1934, about 2,000 cases; in 1938, more than 4,000 cases. Since then, there has been no increase in the number reported. The discrepancy between the actual number and the reported number is discussed further on.

NOMENCLATURE

Nomenclature has played the mischief with brucellosis. Familiar names which suggested erroneous ideas made impressions so deep that they could hardly be obliterated by contrary facts. The two generic names, *Micrococcus*, implying a spherical form of the causal organism of "Malta fever" and *Bacillus*, implying an elongated form of the causal organism of contagious abortion, prevented their comparison until twenty years had passed after Bang's discovery. The names "Malta fever" and "Mediterranean fever" suggested a limited distribution of the disease, and this helped to prevent its recognition in other parts of the world. The name "undulant fever," suggesting that in every case there must be a significant rise of temperature tracing an undulating curve, exerts an influence now against the recognition of the chronic disease.

Some of the unfortunate names have been dropped. When Meyer and Shaw (1920) confirmed the close relationship between strains of caprine and bovine origin, they suggested for this group of organisms the generic name *Brucella*, derived from Bruce, the name of the Englishman who first cultivated the organism from a human case on the island of Malta. This name was accepted, and it is now used in all scientific publications.

The disease is now correctly called brucellosis, a satisfactory name which identifies brucella infection in any of its manifold manifestations in man or ani-

mals. The writer was unable to find the first use of the term "brucellosis," but in 1930 Hasseltine stated that the synonymous terms "brucellosis" and "brucelliasis," signifying the state of being infected with *Brucella*, had recently appeared in the literature, and that the latter term was preferred by classical scholars. Both of these names were used frequently until 1934, when Giltner published a monograph on "brucellosis." In a footnote he explained that "brucellosis" is preferable to "brucelliasis" because the ending *iasis* is used commonly for names of diseases due to protozoan infections, whereas *osis* is used commonly for names of diseases due to vegetable pathogens.

"Brucellosis" is gradually replacing other names, although "undulant fever" still appears in official records in this country. If it should be discarded, that would help to clear the way toward a recognition of the chronic disease.

THE SPECIES OF BRUCELLA

When the close relationship between the causal organisms of "undulant fever" and contagious abortion of cattle was first recognized, the only available test which could distinguish the bovine from the caprine type was the agglutinin-absorption test, which does not distinguish strains of bovine and porcine origins. Later, other tests were devised which enable that distinction to be made, the most practical being the bacteriostatic tests devised by Huddleson.

For the sake of convenience, the various types of *Brucella* have been given specific names. There are three species, *melitensis*, *abortus*, and *suis*. Actually, in the opinion of the writer, they are too closely related to justify the recognition of three species. They differ, however, enough to justify varietal distinctions.

Because trinomials are awkward, recognition of the distinctions as varietal

was not acceptable to the taxonomists.

Susceptibilities of host species—The present incomplete knowledge of susceptibilities to brucellar infection of man and those species of domestic animals in which infection is known to be widespread may be outlined as follows:

<i>Species</i>	<i>Primary Host</i>	<i>Secondary Hosts</i>
<i>B. abortus</i>	cattle	man horse
<i>B. suis</i>	swine	man cattle
<i>B. melitensis</i>	goats (sheep)	man cattle swine

Information is limited on transmission from animal to animal in other than the primary host species. However, a few facts are known.

Although cattle are susceptible to infection with *B. suis*, swine are insusceptible to infection with *B. abortus*. This explains why the disease can exist in the cattle of localities where the porcine disease is nonexistent.

We do not hear of human cases resulting from contact with horses, and this suggests that the infection may not be readily transmitted from the equine to the human subject. A number of investigators (Fitch and Dodge, 1939; Stone, 1941; and others) believe that the disease is transmissible from horses to cattle.

Cattle infected with *B. melitensis* or *B. suis* transmit these organisms to man through the milk. They are more virulent for man than is *B. abortus*, and apparently they do not lose virulence for man on passage through the cow.

Infection of cattle with *B. melitensis* has extended to regions remote from the goat raising country of the Southwest. In 1934 Carpenter and Boak reported that among 122 samples of raw milk from 3 counties in Central New York, brucella were found in 25 samples, and 3 of the strains were proved to be *B.*

melitensis. They came from herds in 3 widely separated localities.

According to data published by Jordan and Borts (1946) it appears that the earliest infections of the swine of this country with *B. melitensis* are of recent occurrence. The first culture of *B. melitensis* from a human case in which the infection was contracted from swine in Iowa was obtained in December, 1943. Since then many cultures of *B. melitensis* have been obtained from human cases in packinghouse workers and farmers. The data suggest that in most of these cases the infection was derived from swine.

The relative percentages of the three brucellar species in the human infections of any locality depend largely on the extent of the development of the hog-raising and/or goat-raising industries. The two following surveys were made in middlewestern states, where the hogs are commonly infected. Kabler and MacLanahan (1936) studied 38 strains which came to the laboratories of the Minnesota Department of Health. Twenty-four were *B. suis*, 12 were *B. abortus*, and 2 could not be satisfactorily classified. Jordan and Borts (1946) reported the distribution of species among 339 strains isolated from the blood in cases of the human disease and studied at Iowa Department of Health from July, 1927, to June, 1945. The distribution was as follows: 67.3 per cent *B. suis*; 24.5 per cent *B. abortus*; 7.7 per cent *B. melitensis*; 0.5 per cent unidentified. That *B. suis* has spread to states where the raising of hogs is not a well developed industry is shown by the data reported from Alabama which were published by Hutchings (1944). Among the cultures from 91 human cases occurring in that state, 69, or 75.8 per cent, were *B. suis*.

Human infections with *B. abortus* tend to be sporadic; those caused by *B. melitensis* and *B. suis* ingested in raw milk are more apt to occur in groups.

In this country many of the outbreaks of human brucellosis traced to cattle have been caused by *B. suis* in raw milk. An outbreak of 11 cases occurred in Georgia in 1929 (Atwood and Hasseltine); one of 30 cases occurred in Iowa in 1933 (Beattie and Rice); one of 14 cases with 3 deaths occurred in a home for elderly persons in Connecticut in 1934-1935 (Horning); one in which 77 persons gave evidence of infection occurred in Iowa in 1941 (Borts, *et al.*).

In 1922 an outbreak of 37 definite and additional suspected cases of brucellosis caused by *B. melitensis* occurred in Arizona. There were two deaths of patients in whom the brucellar infection was superimposed on other chronic disease. In 32 cases the source of the infection was traced to goat's milk (Watkins and Lake, 1927).

THE PREVALENCE OF BRUCELLOSIS

The prevalence of brucellosis in man depends on its prevalence in animals. Hence it is predominantly a rural disease.

Prevalence of brucellosis in cattle—On July 1, 1934, the U. S. Department of Agriculture initiated a campaign for the eradication of the disease from cattle which has been carried on in every state. The criterion of infection is a positive agglutinative reaction of the specific organism in the cow's serum in a titer of 1:100. Reacting animals are slaughtered, and the owner receives partial indemnity. During the first ten years of the campaign about 65,000,000 cattle were tested; more than 2,500,000 were found to be reactors, and were slaughtered. During the first year of the campaign about 10 per cent of cattle reacted to the test, involving 40 per cent of the herds that were tested. The fact that ten years later only about 4.5 per cent of reactors were found attests the success of the campaign in reducing the number of infected cattle.

Prevalence of brucellosis in other

animals—Extensive data comparable to those relating to cattle are unavailable for estimation of the prevalence of brucellosis in other animals. However, limited surveys have been made.

The incidence of brucellosis in swine differs in various parts of the country, being highest in the hog raising states of the Middlewest. Likewise, the incidence of brucellosis in goats is unevenly distributed, being highest in the goat raising states of the Southwest. Holt and Reynolds (1925) found serological evidence of infection in 16.7 per cent of 1,130 goats examined in 22 counties along the Mexican border. Recently Stiles (1945) examined the blood serum of 14,339 animals representing 131 herds in southwestern Colorado, and found evidence of infection in 8.5 per cent of them.

That brucellar infection is common in the horses of this country was shown by several investigators, including Carpenter and Boak (1937) in New York State, and Deem (1937) in Ohio. These investigators found a positive agglutination reaction in a high percentage of cases of fistula of the withers and poll evil, and in a considerable percentage of horses which appeared normal.

Although brucellar infection of sheep exists in France and in other Mediterranean countries, the disease is almost unknown in the sheep of this country. However, it has begun to make its appearance here. Bruce (1930) reported that he had cultivated brucella from a dead lamb received in February, 1927, from Vancouver Island. It came from a flock in which some trouble with lambing had occurred. Apparently the culture was not studied to determine the species of *Brucella*. Bruce believed that this was the first report in North America of brucellar infection of sheep. Jordan and Borts (1946) believe that the recent introduction into Iowa of *B. melitensis* infection of swine was through sheep imported from western and

southern sections of this country. They report one human case of *B. melitensis* infection in which the patient had contact with no animals other than sheep.

A few cases of brucellar infection in dogs have been reported in this country, and the possibility of human infection from dogs is shown by several reports of the transmission of the disease from dogs to man in foreign countries (Dargein and Plazy; Menzani; Mühlenbeck).

Brucellar infection of domestic fowl is reviewed by Huddleson (1943). Little is known, however, of its significance as a source of infection of domestic animals. Infection of rodents, and the possibility that they may serve as a reservoir of infection of domestic animals has been considered by many investigators in foreign countries, and by Fitch and Bishop (1938) in this country. Katz (1941) reviewed the literature on brucellosis in various species of wild animals and discussed the possibility that they may serve as a source of perpetuation of the disease in domestic animals.

The prevalence of brucellosis in man—Approximately 4,000 cases of human brucellosis are reported annually to the state departments of health, and the data are summarized in *Public Health Reports*.

The reported disease, designated "undulant fever," includes acute cases with an undulating temperature curve. It would be impossible to estimate how nearly the reported figure approximates the actual number of such cases, for according to Hughes (1897) and numerous subsequent authors, diagnosis is difficult, even in acute cases. No doubt many acute cases are being missed.

The chronic form of brucellosis is extremely difficult to diagnose. The following lines of evidence indicate, however, that an unrecognized mild form of brucellosis is a common ailment in this country: First, the disease has a

tendency to become chronic in every species of domestic animal in which it has been studied. Second, in many human cases in which the correct diagnosis is finally attained it is only after years of poor health for which no cause could be found. Third, many physicians have found numerous cases after they became aware that there is a chronic form of the disease.

CHRONIC BRUCELLOSIS

A mild form of brucellosis in domestic animals—A general understanding of the course of brucellosis is available without experimentation, for the disease as it occurs spontaneously in domestic animals is known to veterinarians. Its most important feature is the common failure of complete recovery. Every farmer knows the depreciated value of a cow, horse, or hog which has contracted this disease. According to Wight, who has charge of the program of eradication, only one-third to one-half of the cows which become infected with brucella ever recover fully.

In other animals also, brucellar infection is apt to occur in a mild, chronic form, with no obvious signs of disease. Polding (1940) found evidence of latent localized infections persisting in goats for several years following acute infection. Several investigators (Hardy, *et al.*, 1930; Feldman and Olson, 1934; McNutt, 1934) noted that brucella may exist in the tissues of apparently healthy swine. Rice (1944) stated that the exhibition at state and county fairs of infected swine, which appear healthy, is a means of dissemination of the porcine disease. Carpenter and Boak (1937) tested the blood serum of a group of mares repeatedly during a period of two years and found evidence that some of them had become infected without presenting clinical evidence of disease.

A mild form of brucellosis in man—Bearing in mind the tendency of brucellosis to become chronic in various

species of animals which appear healthy in spite of infection, it should be expected that in man also the disease would have a tendency to become chronic. In man, a mild form of brucellosis does occur without obvious signs of disease. It generally fails to be recognized because characteristic signs are lacking and laboratory diagnostic techniques are inadequate.

The following experience, beginning more than twenty years ago, when human brucellosis was almost unknown in this part of the world, is typical of that of many patients at the present time, as revealed in letters requesting information on brucellosis which come to the National Institute of Health. Similar cases are described repeatedly in the growing literature on chronic brucellosis.

In October, 1922, the writer became infected while working on cultures of *Brucella melitensis* received from Phoenix, Ariz. For the first nine months the disease was mild. Medical aid was sought, and after examinations failed to reveal any cause for complaint, a diagnosis of "neurasthenia" was received. Then came an acute exacerbation of typical "undulant fever," so diagnosed when a culture of brucella was obtained from the blood. Then five years of poor health, with complete incapacitation much of the time. Again, medical aid was sought in four successive hospitals. The outcome was always the same, the patient was regarded as "neurasthenic." Finally the impasse was broken by the intervention of another disease which necessitated an operation, during which brucellar lesions were found, from which *B. melitensis* was cultivated. Thus accidentally, at last, came relief from the misunderstandings which must inevitably arise when a patient is said to be suffering from imaginary ills. These misunderstandings are a feature of chronic brucellosis that tries the patient almost beyond endurance.

The literature on chronic brucellosis—The first paper on chronic brucellosis to be published in this country appeared in 1934 (Evans). Since then, numerous authors have discussed the subject (Cameron and Wells, 1934; Angle, 1935; Goldfain, 1938; Roberts and Roberts, 1939; Calder, 1939; Robinson and Evans, 1939; Angle and Algie, 1939; McGinty and Gambrell, 1939; Dustin and Weyler, 1940; Harris, 1941; Goss, 1941; Simpson, 1941; Holbrook, 1942; Manchester, 1942; Hartsock, 1942; Davis, 1942; Urschel, 1943; Griggs, 1943; Schmidt, 1943; Lehr, 1944; Staub, 1944; Chuinard, 1944; Rice, 1944; Benning, 1946). All are convinced that chronic brucellosis is a common disease. Most of them comment on the frequency of the diagnosis of neurasthenia.

Estimations of the incidence of chronic brucellosis—Obviously, estimations of the prevalence of a disease which is so difficult to diagnose as is chronic brucellosis can be only grossly approximate. It seems worth while, however, to record such estimations as can be made.

In 1936, a survey was made of the incidence of chronic brucellosis in Charlotte, N. C. (Robinson and Evans). At the time of the investigation, this city of about 92,000 inhabitants was supplied with raw milk, although many of the herds of cattle in the neighborhood were known to be infected with Bang's disease. Dr. Robinson, who conducted the investigation lasting six months, requested the local physicians to permit him to coöperate with them in studying cases of obscure chronic disease, and he received their generous coöperation.

Although the survey could not cover the entire population of Charlotte, 325 cases of chronic disease were investigated, and among them 22 were regarded as probably chronic brucellosis. In some of the cases this diagnosis was con-

firmed by a positive agglutinative reaction. In 5 cases, blood cultures confirmed the diagnosis.

Considering these results, it would appear to be a conservative estimate to assume that there were at least 25 cases of chronic brucellosis in Charlotte at the time of the survey. If the incidence of the chronic disease in the entire rural population of the United States of approximately 57,000,000 resembles the incidence in Charlotte at the time of the survey, there would be about 35,000 cases in the entire country.

A similar figure is obtained if an estimation is based on the data reported by Lehr (1944). He found that two physicians of St. Clair County, Illinois, who had established a reputation for skill in the diagnosis of brucellosis, together had diagnosed about 100 cases during a period of 2½ years, although they had reported only 2. Lehr studied 24 of their cases, and reported that most of the patients had suffered from ill health for 1 to 4 years before coming under the care of a physician.

All of the 100 cases considered by Lehr were from the rural area of St. Clair County, Illinois, with a population of about 70,000. (The urban population of the county was not considered in these figures because it was protected by an ordinance which required pasteurization of milk.) At the rate of 40 cases per year in an area with a rural population of about 70,000, about 33,000 cases would occur each year in the rural areas of the entire country.

Again, a somewhat similar figure is obtained in an estimation based on a statement made by Gilbert and Coleman (1934). They doubted whether more than one-tenth of the cases that occur in New York State are recognized. It happens that in Italy also, an investigator (Alessandrini, 1938) held the opinion that the number of reported cases should be multiplied by ten, at least, to represent the actual number.

At that rate, the three or four thousand cases reported annually in *Public Health Reports* would represent 30,000 to 40,000 actual cases.

Data published by Huddleson, *et al.* (1937) may be used to obtain a much higher figure for the prevalence of brucellosis. They carried out an investigation in a county hospital in Michigan where a part of the supply of milk was known to be infected with brucella. These investigators found evidence that 7.1 per cent of the 8,124 inmates were infected. If that percentage of the entire rural population of the United States were infected, the total figure would be approximately 4,000,000.

The actual number of persons suffering from brucellar infection in this country during any year probably lies somewhere between 40,000 and 4,000,000. Perhaps the smaller figure may represent approximately the number of persons who are disabled or partially disabled for a considerable time during the year. In other words, it may roughly represent the number of patients with brucellosis who consult a doctor. Perhaps the larger figure may not be too high if it is taken to include mild cases of transitory infection in which recovery is complete after a few days of indisposition, and cases of the chronic disease in which the general health is impaired by a localized infection of many years' standing.

RESEARCH PROBLEMS

A fundamental problem of brucellosis is the discovery of methods for the control of the disease in animals. Urgent from the point of view of both the human and animal disease is the discovery of an effective therapeutic agent. The development of laboratory techniques to facilitate the recognition of the mild form of the disease is important. Many other brucellar problems on which information is incomplete should be in-

vestigated. Some of them were suggested in the preceding pages.

Problems of an Aging Population*

Setting the Stage

LOUIS I. DUBLIN, PH.D., F.A.P.H.A.

Second Vice-President and Statistician, Metropolitan Life Insurance Company, New York, N. Y.

IT is high time that public health officers took notice of the health problems and opportunities centering around the middle and older ages of life. Today's discussion should be a profitable one; it may be historic, if we realize fully the implications in the changes which have been taking place in our population structure and in the widening sphere of influence of the public health profession.

For extraordinary changes have taken place and are continuing to take place in the population of our country. Ours is still a young country, and one of its most striking characteristics has been the low average age of the people. Even today half of our population is under 30 years of age. Until fairly recently our population grew rapidly in numbers. It is well to remember that the entire history of our country, including the period of colonization, is encompassed by only three centuries. Between the first federal census in 1790 and the last in 1940, the population increased to 33 times the original figure. Our people were particularly fertile and their heavy natural increase was augmented by a continuous flow of large numbers of young immigrants from virtually every section of the European continent. The combination of these two factors determined the

age structure of our population. Our country, in contrast to the more settled areas of Europe, had a strikingly large proportion of children and young adults. Every observer of the American scene has commented on this important characteristic.

In view of the large concentration of children and young adults in our population so far in its history, it is fortunate that the timely discoveries of the bacteriologists and the achievements of the sanitarians have been in the field of the infectious diseases—the conditions most prevalent in the early years of life. It is no wonder that the public health activities, in fact, the major part of the public health program, concentrated on the control of this group of diseases. The activities of the health officer and his staff as they developed have centered primarily on such conditions as the communicable diseases of children, the disorders of the puerperal state, on the sanitation of the environment, with especial reference to the control of typhoid fever, the diarrheal diseases, and tuberculosis. In this way, a pattern of health service has emerged which has been fairly well established throughout the land and, let me add, has been extraordinarily successful. Public health work is the crown jewel in the structure of our public services.

This health service, fortunately, has not been, nor is it now, static in character. The public health pro

1950 to 2000 from estimates published by Bureau of the Census 1946

Metropolitan Life Insurance Company

fession has always been ready to adapt itself to new situations, to try out new procedures, and to widen its sphere of influence. Being a relatively young profession, it has the vigor and resourcefulness of youth. It is now confronted with a new and enticing opportunity for valuable service brought about by the very success of its previous endeavors and by the changes which have accumulated in the population structure of the country. That is what we are concerned with at this particular session.

The fact is that our country is rapidly settling down to a new demographic pattern. From the beginning of the century, our birth rate has dropped about one-third. Immigration has been drastically cut in the period since 1924. As a result of these two forces, and the increasing numbers surviving into middle and later life, there has been a marked shift in the distribution of our population, from youth to the older ages. Chart 1 illustrates what has happened and what is likely to happen in the course of the next two generations.

Thus, in 1900, less than one-fifth of the population was 45 years or more in age; by 1940, the ratio had increased to more than one-quarter of the total. This trend will continue for many decades. Careful forecasts indicate that by 1960 almost one-third of our population will be 45 years of age or over, and that, by the end of the century, two-fifths of the people will be in that age category. If we concentrate on the group 65 years and older, the changes since 1900 and those in prospect are even more striking. Thus, at the turn of the century, this older group included 4.1 per cent of the population. By 1940, the figure had increased to 6.8 per cent and, by 1960, the best indications are that over 9 per cent will be in the old age bracket.

Obviously, the progressive health officer is taking note of these striking changes. He will see that the whole community picture is taking on another aspect. He will not rest upon his past achievements and let slip opportunities for services as important, even if not so dramatic, as those which confronted his

CHART 2

RANK AND DEATH RATES FROM TEN LEADING CAUSES IN 1944 COMPARED WITH THE SAME CAUSES IN 1900

predecessors 30 and 40 years ago. The public health program must adjust itself to the problems and demands which arise from the new demographic set-up.

As an indication of the changes that have taken place even within our own time, let us compare the leading causes of death today with what they were at the beginning of the century (see Chart 2). At that time, the first and second ranks among our causes of death were held by two infectious conditions, namely, tuberculosis and pneumonia; these two causes alone then accounted for over one-fifth of the total mortality. Since that time, they have fallen to sixth and seventh place in rank and now constitute barely one-twelfth of all deaths. Of the first five causes in order of magnitude, in the present situation, four—heart disease, cancer, cerebral hemorrhage, and nephritis—are diseases characteristic of middle life and old age. Diabetes and arteriosclerosis, the eighth and tenth in order of rank, are likewise typical conditions at these stages of life.

Altogether, these six causes account for over three-fifths of all deaths registered in 1944, the last year for which country-wide figures are available. Even in the case of the two infectious diseases appearing in the list for 1944, pneumonia and tuberculosis, 54 per cent of the deaths occurred at and after age 45.

The age picture of mortality has thus greatly changed. In 1900, only 40 per cent of all deaths were at ages 45 and over; today, about 75 per cent fall into these ages. By 1960 more than four-fifths of all deaths will be at age 45 or higher, and the proportion will rise to more than nine-tenths by the end of the century. In so far as the public health officer is concerned with the mortality situation, he must concentrate his activities more and more on the diseases and conditions which affect the older ages.

Morbidity data likewise reflect the changes we have described in the age structure of our population. Every hospital director and every director of a

nursing service has felt the impact of these changes in recent years. The pattern of disease incidence, like mortality, has shifted to feature the conditions at the older ages. Thus, in the country-wide Metropolitan nursing experience for policy holders in 1925, nearly 50 per cent of the cases were nursed for the acute and communicable conditions, most of which occur in early life, and only about 5 per cent were for the chronic diseases—conditions typical of old age; in 1945, on the other hand, the two figures were 14 and 28 per cent, respectively. A complete reversal in emphasis has taken place. Recent sickness surveys, including especially the National Health Survey of 1935-1936, show how great the burden of invalidism has become at the older ages. If the age frequency of invalidism as observed in the National Health Survey prevails in our current population, then 70 per cent of our invalids, that is, persons permanently disabled, are at ages 45 or higher; by the end of the century, 80 per cent of the invalids will be in this age range.

The health officer of today, freed from many of the community threats of his predecessor, must take on the new challenges which confront him. More and more, he must adapt his services and his facilities to the needs of those who are now presenting him with a whole host of health problems. It is not for me, in these preliminary remarks, to discuss the specific functions which the health officer may well take on in serving the health of the middle aged and older people. That will be done very well by those who follow me in this program. All that I wish, in addition, is to point out how great are the opportunities for substantial accomplishment if the situation is approached seriously and the necessary adjustments in personnel and facilities are made.

Let us take, for example, the problem of cancer which Dr. Lombard will dis-

cuss. How many of us realize that this disease is responsible for shortening the average remaining lifetime of those entering middle life by about $1\frac{1}{2}$ years. If we could make a dent in this condition from the preventive aspects, a very significant contribution would be made. The same is true with reference to the cardiovascular-renal conditions. The diabetes problem, which Dr. Wilkerson has as his subject, will grow rapidly in importance as our population ages. If, through the more extensive application of the health services of the country, be it through health education, the development of special diagnostic clinics, or the provision of medical and nursing care, we could reduce the volume of invalidism from these conditions at the middle and older ages, we would not only add appreciably to the life expectation but also increase the productive capacity of the country.

It is not suggested that the entire burden of the diseases of middle and old age shall suddenly be assumed by the public health services of the country. Obviously, the largest measure of care for this older group of the population must remain in the hands of the practitioners of medicine and an increasing measure be left to the ministrations of the voluntary health agencies. What we are attempting today is to clarify the rôle which the official health agencies may play as partners in this three cornered set-up of medical service, preventive health service, and friendly social service, working together in order to meet a great public need. I am confident that, as the years roll by, a larger share of the time and resources of our health departments will be concerned with the prevention and care of the disorders which afflict the middle and older years of life. It is not only the opportunity but the duty of the public health profession to prepare itself for this service.

Problems of an Aging Population*

Care of the Aged and Chronically Ill

THEODORE G. KLUMPP, M.D.

President, Winthrop Chemical Company, New York, N. Y.

A CENTURY and a half ago, Horace Walpole wrote these lines: "About the time, or a little later, I die, the secret will be found of how to live forever." Feeling that enough time had passed to vouchsafe a reply, Helen Bevington answered:

Horace, be comforted to die.
One century has meandered by
And half the next since, it was true,
The temporal state eluded you.
Now as I read your pensive letter,
I wish myself that times were better
And I might boast how men contrive,
As you foretold, to stay alive.
By now we should possess the key
To fleshly immortality
And, if we wanted to, endeavor
To live forever and forever.
This, to my infinite regret,
Is not a custom with us yet.

I write you Horace for good cheer
Life is about as usual here.

Unfortunately, life is about as usual here so far as our knowledge of the nature of the aging process and many chronic diseases is concerned. In the past we have been largely preoccupied with the diseases of youth and childhood. Our chief endeavor was to learn to run the gauntlet of infections so that we might raise a reasonable number of our children to adult life. We have not yet finished this job and we never will altogether—but mortality statistics show that we have made great advances for which our physicians, research workers,

and public health officials can feel justly proud.

But, as a result of our success in conquering infections and some of the most deadly diseases of childhood, we now have an adult population that is larger in proportion than it has ever been before. It promises to grow even greater as the years roll by. This poses new public health problems, and hitherto neglected diseases assume compelling importance. The care of the aged and chronically ill must not be left to the old man with the long white beard and the scythe.

In a sense we are now standing where the stream divides. For generations we have followed the branch of infectious diseases. It has dwindled in size, but we have not yet really started the exploration of that other stream that flows in the direction of the chronic diseases of adult life and geriatrics. A whole new field of knowledge is waiting to be studied and mastered. We have not even begun to think seriously about the sociological and public health aspects of old age and the chronic diseases. Neither medicine, nor industry, nor the State, has any carefully thought out program of what to do about the vast population of older persons that is rising in our midst. Only Dr. Townsend has a \$50 every Friday plan which most other doctors feel is not the answer.

Our research has not scratched the surface of such problems as heart disease and coronary thrombosis, nephritis, arthritis, and cancer. We know more

* Presented before the Health Officers Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 14, 1946.

about the planet Mars than we know about the pathogenesis of arteriosclerosis which is probably the least common denominator of most of the disabilities of the aging process.

Some indication of the increasing importance of the problems to which I have alluded may be gained from figures on the percentage of our population in the older age groups. According to U. S. Census figures, and reliable estimates with respect to the future, the following represents the proportion of our population 45 years of age and over:

	<i>Per cent</i>
1860.....	13.1
1880.....	16.0
1900.....	17.8
1920.....	20.8
1940.....	26.5
1960.....	33.3
1980.....	40.3

When we consider those 65 years and over, the following percentage distribution is reflected:

	<i>Per cent</i>
1860.....	2.7
1880.....	3.4
1900.....	4.1
1920.....	4.7
1940.....	6.8
1960.....	10.0
1980.....	14.4

The important facts to be derived from these data are that the weight of our population is shifting toward the older group, and by 1980 two-fifths of our population will be over 45, and one-seventh over 65. At the same time the total number of our people is also increasing. It has been conservatively estimated that we will have not less than 150 million people by 1980. This means that by that time there will be not less than 60 million 45 years and over and over 21 million 65 and over. Think of it, 21 million persons 65 and over! These figures have special significance in the light of the all-time employment record which has just been announced by the President as 58 million gainfully

employed. This means that in less than 34 years we shall have more individuals over 45 years of age than the total number employed at the present time. We must also anticipate the continued introduction of new labor saving devices, perhaps on a scale never dreamed of before. The technologies recently developed, particularly in electronics, and the upswing of interest in science generally should provide for that. If we do nothing about it, and maintain present-day working standards and conditions, we shall have a potential labor surplus of over 30 million workers by 1980.

And now let us for a moment turn to the chronically ill. According to the U. S. Public Health Service the number of persons in the United States suffering from certain chronic diseases in 1937 was as follows:

Arthritis and rheumatism.....	9,700,000
Heart disease	3,700,000
Hay fever and asthma.....	3,450,000
Chronic bronchitis	1,700,000
Nephritis and kidney disease.....	1,550,000
Nervous and mental diseases.....	1,450,000

These are only a few of the chronic diseases. The list would be too long to mention them all. We have not taken into account such seriously disabling diseases as diabetes, thyroid diseases, blindness, tuberculosis and other chronic infections. It has been estimated that in 1943 there were 25,000,000 suffering from chronic ailments, with an annual disability rate of 1 billion man days, and approximately 1 million deaths a year from the same cause. Add to this 9,700,000 individuals partially or totally disabled from accidents and it may be seen that we have a problem on our hands that is greater than most people realize. As the number of older individuals in our population increases, this problem too will become accentuated.

What are we to do about the aged and the partially disabled? We cannot plow them under as we used to plow under corn, potatoes, tobacco, and little

pigs. And I am equally certain that we cannot just turn them out to pasture and expect them to enjoy life. People are not happy when they are idle, and this is particularly true of older individuals. Youth can loaf content with opiate dreams of future achievements. But as we grow older the realities of life are more clearly seen and less easily denied and as we approach 50 and 60 we can no longer derive solace from the pipe dreams of future achievements. Similarly the diversion of participation in sport and exercise is denied us. Age plays for real stakes, not pastime. It wants something to do and it must be real. And the most real thing we have to sustain us in this life of ours is useful work for which we are paid in money or in kind. Have you seen, as I have, a faithful employee who has been working at his job for 20, 30, or 40 years and wants to continue? Have you seen such an employee "retired" to the boneyard by some blind compulsory retirement scheme? There is an unutterable sadness about it that sometimes makes me think that it would be kinder to shoot the old fellow. I believe I understand why so often they die shortly after retirement.

Any biological organism that has been accustomed to a set routine for 40 or 50 years cannot suddenly be shaken from its orbit without untoward consequences. Anyone who has studied Cannon's ideas on homeostasis will recognize this.

Our society has been quite illogical and inconsistent in its attitude toward the older worker. On the one hand it is apparent that we have no objection to electing and appointing older individuals to positions of the greatest responsibility in government, business, and the professions. For instance, in the present Congress 32 Senators, or 41.3 per cent, are over 65 years of age, 12 or 15.3 per cent, are 61 to 65 years of age; in other words, over 56 per cent are over

60. In the House of Representatives, 57, or 21.3 per cent, are over 65 years of age, and 36 representatives, or 13.4 per cent, are 61 to 65 years of age. A study was made of top business executives as listed in *Poor's Directory*. Taking 500 consecutive names contained therein it was found that 143, or 28.6 per cent, of those listed were over 65 years of age, 78, or 15.6 per cent, were between 61 and 65 years inclusively. Here again, over 44 per cent are over 60 years of age. I am certain that a study of the leadership of the various professions would reveal the same large proportion of individuals in the older group.

And yet as far as the rank and file of workers is concerned we have no objection to the imposition of blind and unselective compulsory retirement rules which automatically eliminate those in the ranks who have reached the same age regardless of their fitness, ability, and contribution to the group for which they labor. More precious than oil or fertile soil, than ore and minerals, than trees or an equable climate, are the human resources of a country. All other things were here when Columbus discovered America, but it took intelligent, industrious men to make our country what it is today. We may not fully realize it, but we cannot afford to waste the contributions of those who through years of experience have learned to do their jobs well and are willing and able to continue faithfully. Training and experience can only be replaced by training and experience, and when we retire a competent older worker his successor has the burden, inevitably, of supporting the man he replaces as well as himself.

Some individuals welcome retirement, and the possibility of voluntary retirement on a pension should always remain open for these. But if the premise is that all individuals over 65 or 70 are not worth their keep, then least of all should we permit individuals above

those ages to occupy the top and critical positions in our social structure. If we acknowledge, as is certainly true, that some are and some are not fit at those ages, then we should use our intelligence to devise methods of determining which are and which are not fit for all workers, not just the upper crust. As the great physiologist, A. J. Carlson, stated: "The physiologic age of the worker is not synonymous with his chronologic age, owing to the individual variables in heredity, mode of living, accidents and sequelae of disease." Likewise, "All age changes come on gradually," according to Carlson, and we know now that in some individuals changes characteristic of senescence begin even in childhood. And biologically we all start to grow old the moment we stop growing.

That such changes may proceed very gradually and slowly is illustrated by the fascinating and possibly authentic story of Christen Jacobsen Dragenberg reported in the *Journal of the Institute of Actuaries*. His manner of life may be instructive for those who seek longevity. Dragenberg was a Dane who lived to be 146 years of age from 1626 to 1772. He went to sea when he was 13, took part in the wars of three kings against Sweden, served many nations in merchant navies, when nearly 70 was taken prisoner by Algerian pirates, was sold as a slave, escaped slavery after 15 years, and at 84 again went to war against Sweden. At 111 he married a woman of 60, outlived her, proposed at 130 to several women but was rejected. Mastering his disappointment, he lived on for 16 years. Described as being of impetuous temperament, he lived a life far from blameless, but in his last 5 years, from 141 to 146, exhibited a conduct "quite respectable."

We choose and select when we hire, and I see no reason why we cannot do the same thing when we retire our workers. In 1930 on the basis of a compulsory retirement rule, the most dis-

tinguished neurological surgeon the world has yet known, Harvey Cushing, was retired from the Harvard faculty at a time when he was at the peak of his ability. He promptly accepted a full-time academic appointment at Yale where he continued his outstanding contributions to medical science. What was Harvard's loss was Yale's gain, but for Dr. Cushing the retirement rule meant only the waste of time and inconvenience of pulling up stakes, moving, and finding a new home.

When Dr. Milton J. Rosenau was retired from the same faculty he too moved to another university where the rules were not so blind. From a sociological standpoint the whole thing is ridiculous, and a reflection on the state of our intelligence in solving what ought to be a simple problem. Whenever society adopts a rule that eliminates the fit with the unfit, destroys the good with the bad, or punishes the innocent with the wicked, it is not a good rule. Society progresses by changing rules of this kind. In an imperfect society human beings are pushed around as a faceless mob. But social progress may be measured in the last analysis by the degree of skill and discrimination with which society solves the individual problems of its members.

The argument has been advanced that we must clear out the older workers to make room for the younger men so that their progress upward in an organization will not be unduly retarded. On the face of it this line of reasoning appears to have some merit. But it is only another way of stating that there are more workers than there are jobs. During the war when there was a man power shortage no one was afraid that the old, the lame, the blind, and the halt, were taking jobs away from younger and more able workers. At other times similar arguments have been applied against the employment of women in business, government, and the profes-

sions. Certainly there is no arbitrary age at which older workers begin to repress the advancement of younger individuals. In a sense, every older individual higher on the ladder of advancement, whether he be 65 or 55 or 45 is holding a job that a younger individual aspires to and feels he can fill. That is always true and it will be just as true if we force everyone to retire at 50 or even 45 as we will have to do by 1980 if we do not find a more logical way of reducing the disparity between jobs and workers.

We must not lose sight of the fact that someone must support those that we retire to idleness. The more workers we eliminate, and particularly if we should lower the retirement ages, the greater will be the economic burden we will place on those who do work. They will have to produce enough to support themselves and their families as well as the increased numbers of those who become emeritus workers. The whole problem is the adjustment of the number of workers to the number of jobs available. To attempt to strike a balance by eliminating all workers over a certain age is an unfair penalty on age and experience. In a refined and delicate way it is a perpetuation of the jungle law of the fang and claw where the leaders of the pack survive only until the younger beasts grow fierce enough to eliminate them. In modern civilization we are less violent but the end result is approximately the same.

One of the most important steps in solving this problem is the successive reduction in working hours for all workers rather than by reducing more and more older workers to a state of parasitism. I venture to say that you and I will live to see a thirty hour week in industry.

Another view that is widely held is that older individuals become over-conservative, and to make progress we must eliminate these obstacles in the path of progress. Here again there are

such wide variations in human reaction patterns that I do not see how one can logically draw generalizations that will fit individual cases. Certainly Bernard Baruch, 76 years of age, is no obstacle in the path of progress, and neither Senator Pepper nor Henry Wallace has become more conservative as he has grown older. As far as the great mass of jobs now subject to compulsory retirement is concerned, it makes no difference at all whether an individual grows more or less conservative. If individuals in key positions become too conservative with age or even too reckless, as they sometimes do, to meet the best interests of the organization, a retirement board operating on a selective basis can function to correct this development, as well as any others that may arise.

The war has given us a slight stimulus toward finding jobs for partially disabled workers. We have not yet developed this as far as the German ulcer battalions are concerned, and a great deal of educational work remains to be done with industry and government. When a worker is physically handicapped in one respect he tends to compensate for this handicap by development in other directions. This biological mechanism of compensation serves to make such workers perhaps even more valuable than normal workers in the tasks which they are fitted to perform. We have a vast educational job to perform here and it seems to me that those who are interested in industrial health and welfare should lead in this endeavor.

During the past decade industry and our federal and state governments have made great advances in provisions for the care of the aged. What we have accomplished is only a start and much more remains to be done. I am hopeful that the major burden of this can be carried by the extension of voluntary retirement plans in which the employer and the employee share the cost. Not

only must more realistic retirement benefits be provided, but such plans must be more widely adopted by employers generally. The problem of transferring retirement benefits without loss when an employee moves from one job to another remains to be solved. Under present-day practices a worker who changes from one job to another to advance himself, or for any other reason, is penalized by loss of the portion of his retirement accumulation which the employer contributes. For those not covered by adequate voluntary retirement programs, the present token social security benefits must be increased, and old age assistance on a lower scale provided for those who, for one reason or another, have failed to earn their share of the retirement burden.

Through workmen's compensation and health, accident and disability insurance we have also taken important steps in caring for those who are chronically ill and partially or totally disabled. Here again we have only made a start. There is room for improvement not only in the provisions made for the economic care of these unfortunates, but also in the medical and institutional care made available. We can understand why general hospitals wish to avoid having their beds filled with "chronics," but we will need an ever increasing number of institutions devoted solely to these cases.

While social advances in the direction I have indicated will cost money, there is no contribution we can make to human welfare and happiness that is of greater fundamental importance. Compared with the tax burden of war and armaments, which human ingenuity should be capable of eliminating, it is negligible. Even this tax burden can be lessened by permitting capable and willing older workers to continue working, and finding more places in industry and government for those partially disabled.

As we progress to a more perfect civilization, the goal of which is nothing more than a greater measure of happiness for all mankind, there is much that remains to be done for those that are aged and chronically ill. The following general principles will, in my opinion, serve as a guide toward this end:

1. Since physiological age is not synonymous with chronological age, compulsory retirement on a calendar age basis should be abandoned.

2. Since hiring is selective and based on fitness to do a given job, retirement should likewise be selective and based on unfitness. If we can do one there is no reason why we cannot do the other.

3. Compulsory retirement should be based on the recommendation of a retirement board composed of medical and psychiatric members as well as administrative officials.

4. In accord with Carlson's idea, if wage in proportion to performance is recognized as a fundamental principle, the older worker should taper off in industry, just as the young apprentice gradually works himself up in skill, performance, and remuneration. In other words, opportunities for down grading in position and salary should be offered. If this becomes a general practice, the aura of foolish pride which now stands in the way of this would soon disappear. The older worker can choose retirement if he does not like the idea.

5. Industry, governmental and private institutions must make a greater and more intelligent effort to employ partially disabled persons.

6. When the aged and disabled have work to do they are less of a burden, financially, socially, and spiritually to the folks at home. Other things being equal, home environment is better than an institution for the aged and disabled, and the strong and fit must learn to exercise a greater measure of patience, tolerance, and kindness toward them.

7. Institutions for the aged and disabled must be changed from asylums to modern institutions where every convenience and scientific development is available for their physical, mental, and spiritual comfort. The importance of occupational therapy must not be forgotten. Useless work such as basket weaving is not the answer. Under ideal conditions each institutionalized person will have a job tailored to fit his ability and aptitude and for which he will be paid in proportion to his production.

This paper has only one purpose: To emphasize the growing importance of

the problem of the aged and chronically ill. It is a plea for the the devotion of more thought, more research, and more funds to improve the lot of the largest and most neglected group of unfortunates in our society. It is from those interested in public health and welfare that we may expect leadership in this endeavor.

Old age is not a disease but the disabilities arising from it are. As we overcome these we not only postpone old age but we defeat the suffering and sorrow of old age.

Death has its final victory but it can come in peace, even as it came to my teacher and our late President, Dr. Milton J. Rosenau.

Problems of an Aging Population*

Sheltered Care of the Aged

JOSEPH H. KINNAMAN, M.D., M.P.H., F.A.P.H.A.

Deputy Commissioner, Nassau County Department of Health, Mineola, N. Y.

NOW that Dublin has set the stage the relative importance of the medical-social problems of older persons are clearly seen against a proper backdrop. There are abundant signs that others are discarding those concepts of administrative practice which were based on 19th century census figures and a pastoral existence. Only a few examples need to be cited.

Federal social security legislation is one of the many signs that Congress is showing increasing concern for the basic needs of all the people. The appointment of state commissions to plan the development of hospital and other facilities for the care of the sick, aged, and handicapped persons is another indication. The mushroom growth of privately operated convalescent and nursing homes and of supervised boarding homes reflects the appreciation on the part of many people that the demands for medical, nursing, and custodial services outside the patient's own home are increasing.

The older person's own home or that of a relative still represents the most available and best facility for providing sheltered care for the aged and infirm. Yet many factors or combinations thereof frequently operate to make it physically impossible, medically unsafe, and socially unsound or uneconomical for older persons to have their needs met in such homes. A home will not

always be available to an older person. A family unit, even though willing to provide care for a relative or friend, may be unable to do so for a host of obvious reasons, not the least important being that housing itself is a major national problem. Community resources, such as bedside nursing, housekeeper aide, and rehabilitation training services, frequently have not been adequately developed to supplement the private home care of the ill or convalescent older person.

Every older person might be placed in a private home. (One authority estimates that 85 per cent of the chronically ill are now being cared for in their own homes.) As much and as good care at reasonable costs to the individual and the public might be provided. Yet, under certain circumstances, removal from the home and placement, at least temporarily, in another type of facility would be medically indicated or socially desirable. For example, hospitalization for major surgery is medically indicated. Placement in a convalescent or nursing home may be required in order to secure specialized nursing services; to complete the patient's restoration to health or to attain maximum arrest of a disease. For those older persons who are incapable of recovery, custodial care in a medical domiciliary institution may be socially desirable.

Care of the chronically ill and aged infirm outside of a private home or a hospital is usually given in facilities that have been termed by Rogers¹ as "nurs-

* Presented before the Health Officers Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 14, 1946.

ing infirmaries," by Wagner² as "between hospital and home facilities," and by Griffin³ as "commercial homes." Commonly these facilities are privately operated, but interest in this country for partial or complete support of "nursing infirmaries" with public funds is increasing. Public support of such facilities has developed earlier and to a greater extent in Great Britain than here.⁴

Convalescent or nursing homes, county or city public homes and their infirmaries, voluntary homes for the aged, small proprietary hospitals and supervised boarding homes are all types of sheltered care facilities.

A nursing home may be defined as a medical care facility in which sick, infirm, or handicapped persons not requiring hospitalization are provided with shelter, board, and essential nursing care under medical supervision.

Privately conducted homes for the care of the chronically ill, aged or infirm are rarely if ever adequate to meet the needs. All too frequently these homes provide a poor quality of care. Needs of the older persons in them are seldom the basis for service. The cost to the individual (and to the taxpayer, since public recipients are commonly placed in these homes) bears little if any relationship to the quantity and quality of care given. Buildings designed and constructed for use as nursing homes are seldom seen in the New York City area unless they are either publicly or philanthropically financed. Buildings built specifically for use as homes for the aged have been built with funds raised by fraternal, religious, or nationalistic organizations. Nursing homes almost invariably are conducted in large buildings, usually constructed of wood or other combustible material, that were intended for some other use, especially as single family dwellings. Such structures can never be made fire-safe.

Training or experience in nursing is rarely required of operators, even though nurses of one kind or another usually conduct most of the nursing homes. The bed capacity of such homes is usually limited and the nurse operator commonly assumes the combined duties of business manager, cook, housekeeper, and nurse. Presumably, schools offering approved courses in nursing home administration do not exist. If they do, operators in this area apparently have not taken sabbatical leaves. At least, the majority of operators of convalescent homes show little understanding or appreciation of the principle that convalescent care, to be truly effective, must be of such quality as to offer the maximum opportunity to the patient for rehabilitation and return to a period of economic usefulness and happiness. In Nassau County, New York, none of the eighteen privately operated nursing homes has medical services affiliated with the staff of a secondary hospital center as recommended by Rogers.¹

Potter^{5, 6} and Jarrett⁷ have discussed more fully the shortcomings of presently available facilities of this type, and these authorities have also suggested remedies.

By 1946 at least 21 states were licensing either nursing homes alone or the gamut of medical care facilities. This is in addition to legislation dealing with facilities for mental diseases and tuberculosis, which legislation was enacted by many states years ago. Eight states require licensure of all facilities caring for sick and handicapped persons. In all states having this comprehensive coverage the health department is the licensing agency.⁸ At least 13 other states have laws requiring the licensure of one or more types of facilities caring for the sick or handicapped.

The licensing agency in 7 of these is the state department of welfare; in 5, the state department of health; and in

1, New Jersey, a special state department. Facilities under certain auspices, such as federal, state, county, or local government, commonly (unfortunately) are specifically excluded from licensure. A license fee is required by most states. The license period is usually one year, not necessarily the calendar year.

The purpose of supervision is to improve the quantity and quality of the *total* services rendered to the consumer. Much of the present-day emphasis in supervision is on safety from fire, sanitation of the environment, and adequate provision for the basic needs in maintaining life. All of them deserve attention. However, the important thing to remember is that the consumer, in such a facility, pays for and is entitled to receive quality attendant and nursing care under medical supervision. Consequently, unless supervision is concerned with the quality of medical, preventive, and health services, these facilities will not make an effective and necessary contribution to the total medical care program of a community. If the development of a "what's the use" attitude on the part of many older persons in these homes is to be prevented, supervision must be extended to include provision for a full social life according to the individual's physical and mental strength and capacity. Efforts to "add life to years, not merely years to life" have been amply rewarded according to Wagner⁹ and Gorrie.¹⁰

The application of this philosophy of supervision requires that all the habits and thoughts of many people regarding "between the hospital and home facilities" be changed. Education is, therefore, a fundamental part of supervision. Medical practitioners, operators, and staffs of such facilities, members of the inspectional force responsible for supervision, appropriating and other officials, and the consumer public—all must be moved to assume their respective and collective responsibilities for super-

vision. The fact that a purposeful and well directed educational approach results in sustained improvements in services and in their extension has been amply demonstrated in connection with many other areas of medical-social service. Education is fundamental to integration of services and to the economic use of facilities.

Licensure of facilities for caring for infirm aged or chronically ill older persons is only one of the several responsibilities which government has for meeting the needs of that group. Far more important than licensure of institutions, and providing for it whenever indicated is an integrated approach to all of the medical-social problems involved in providing sheltered care for the aged. Such an approach holds the only real promise that a happy and satisfactory solution will be found for them.

Facilities are the great need today. They must be thoroughly practical and fully correlated with existing resources. In the final analysis, the achievement of the goal of having available to all who need them safe, sanitary facilities capable of providing medical, preventive, health and social services based on the needs of the whole person and dedicated to the purpose of returning, whenever possible, that older person to his own home and to a life of economic usefulness, will depend upon our social enlightenment and our willingness to provide for others those things which we most want for ourselves.

The reasonableness of developing plans for these facilities on a state-wide basis is generally supported. Integration of the findings of several study commissions keynotes the New York State approach. There a subcommittee of the (Ostertag) Joint Legislative Committee on Interstate Coöperation is undertaking a study of adult institutional care. The New York State Health Preparedness Commission is completing a study on the care of the chronically ill

and its report probably will include a section on nursing (and related) homes. The Joint Hospital Board of New York State is conducting a survey and developing a state-wide plan for hospital and health center facilities. Other studies of related problems also are in progress in this state.

The State of New York does not require licensure of nursing homes. The State Department of Social Welfare requires, however, that local departments of welfare "certify" to it, those nursing homes used for care of recipients of public assistance. The cities of New York, Yonkers, Mount Vernon, New Rochelle, and Syracuse, and the County of Nassau have ordinances specifically governing the establishment and operation of such homes.

Nassau County lies just east of New York City and is on Long Island. Since 1938, a full-time county department of health has served its semi-urban population, which now totals more than 460,000. Soon after the establishment of that department, Health Commissioner Earle G. Brown proposed that nursing homes be licensed, but this action was not taken then because the Administrative Code of the county did not provide for it. Later, as a result of a newspaper exposé of conditions in nursing homes located in the county, that Code and the Nassau County Public Health Ordinance were amended to provide for licensure of such homes, effective October 1, 1941. The provisions of that ordinance are essentially the same as the regulations governing nursing homes of the Department of Hospitals, New York City. In Nassau, the county department of health is the licensing agency.

When licensure was inaugurated, although inspection disclosed the need for general improvement, only a few were unsatisfactory. Only 1 of these 20 private institutions was being conducted in a fire-safe building, which was designed

and constructed specifically for use as a home for older persons; the other 19 generally lacked adequate safeguards against fire.

The total bed capacity of all within-the-county facilities, excluding boarding homes, but including public institutions, is less than 800, or approximately 53 per cent of the required capacity proposed by Stone.¹¹ The combined capacity of the 18 private nursing homes is slightly in excess of 500. The County Home and Infirmary provides sheltered care for approximately 138 persons. A county home for ambulatory, non-handicapped persons, Jones Institute, has a maximum capacity of 100. General hospitals, particularly Meadowbrook, a county-maintained institution, provide care for a small number of chronics.

In 1945 recipients of public assistance occupied beds in 60 per cent of the private nursing homes operating in Nassau County. The county department of public welfare used two, including the largest, of three such facilities having a bed capacity of 50 or more. One out of every four of the total beds available in private nursing homes was occupied by a recipient of public assistance. At least 30 assistance cases were being cared for in facilities located outside the county. The county department of public welfare also placed recipients in "foster homes" and in boarding homes.

Administrative problems encountered in connection with the regulation and supervision of nursing homes have resulted from (1) the number of governmental officials involved in licensure; (2) the habits of thought and action of public officials, some of whom are not directly concerned with licensure; (3) the language of the regulation, which frequently makes possible more than one interpretation of the intent; (4) the inability of operators to secure adequate and qualified personnel, especially

nurses, and needed materials for structural improvement; (5) the acute shortage of beds in general hospitals and allied medical facilities; (6) the number of older persons suffering from mental changes of non-committable character; (7) the fact that the present provisions of the federal Social Security Act preclude payment of benefits to individuals in public institutions; (8) the fact that the New York State law does not make care in a public institution a reimbursable item and, conversely, that in this state, care in a private nursing home is a reimbursable, medical item.

Some things have been done in Nassau County that seem to warrant application elsewhere. To secure for all nursing homes the required certificate of conformance or approval covering zoning, building, and fire, from officials having jurisdiction, the Nassau County Department of Health has to deal with a minimum of 15 authorities. Those officials had to be brought together for the purpose of securing the greatest possible uniformity of attitude and action. This has been done through conferences and by the inauguration of "team" inspections. Through conferences with zoning, building, and fire officials, the department has been able to secure a statement of minimum requirements for fire and building safety which every local inspector will enforce. The department has been able to give written notice to all nursing home operators a full year in advance of the effective date of any new requirements of fire and building authorities.

Inspection by a "team" has merit because all persons responsible in any way for licensure have an opportunity to see the home under the same conditions; all findings can be integrated and recommendations agreed upon; the operator is informed at the time of the inspection of all violations, and recommendations are summarized. Subsequently the health department makes a

written summary of all findings and recommendations. A copy of this report is placed in the hands of the operator and all officials concerned. When inspections of nursing homes are made independently by fire, building, health, and welfare officials, the fact that these homes are medical care facilities is not sufficiently impressed on the minds either of the officials or of the operators. Not uncommonly zoning regulations prohibit operation of commercial homes in a village because they are considered undesirable. When prohibition results for that reason it would appear that the need for and the contribution that nursing homes make to the total medical care program of the community have not been effectively emphasized by the licensing agency.

Administration has been made more effective through other uses of education. An institute on nutrition was offered to nursing home operators. Attendance was excellent. Public health nurses and medical personnel on the staff of the department periodically review medical and other records which are required of nursing home operators.

A consultative and advisory service has been initiated by the department. Such services are available to existing operators, to those who plan to open nursing homes, to public officials, and to the general public. One of the practical values of such services to prospective operators is protection against rental or purchase of a building which either cannot be used because zoning ordinances prohibit or cannot be economically converted for use as a nursing home. Those operators who plan to remodel or to extend their facilities are assisted with the practical planning for such changes. It would be helpful to officials and operators alike were the U. S. Public Health Service to prepare suggested plans and specifications for nursing homes as it has already done for hospital and health center facilities.

The department has assisted operators in securing priorities for equipment and materials and by putting them in touch with nurse registries. Frequently information is made available to members of the medical profession and the general public regarding availability of beds in nursing homes. This information service has also been utilized by public officials, notably welfare officials.

The Nassau County Department of Health requires the reporting of all accidents which happen in nursing homes, irrespective of evident injury therefrom. The department then investigates the conditions under which these accidents occurred. Such vital data are generally not available in "Accident Facts." They are obviously a necessary basis for the formulation of a program for prevention of accidents in such medical care facilities.

During 1945 the County Department of Health, public welfare and fire prevention agencies jointly considered existing nursing home facilities in relation to need, and filed recommendations with the Office of the County Executive. One of the recommendations was that consideration be given (1) to the full utilization of existing community resources, including public facilities, for the care of the sick, infirm, and handicapped older persons; (2) to the development and maintenance of additional public facilities, for example, a county nursing home; and (3) to the admission of paying patrons to such public institutions. The County Executive has recently announced that Meadowbrook, a county operated general hospital, will be enlarged from 250 to 600 beds, and that a chronic disease unit is to be included in the plans for expansion of that facility. Primarily because the state law does not now permit reimbursement by the state to local governments for expenditures made by the latter for the care of recipients of public assistance in tax supported insti-

tutions, no county nursing home or other medical domiciliary care facility is eventuating. This suggests the need for amending the New York State law, so as to encourage communities to provide adequate medical care facilities.

The urgent need for beds, which cannot be met by the combined capacities of private and public nursing home facilities of this county, has resulted in a tendency to aggregate older persons in so-called boarding homes. When a home is, in fact, a boarding home and not a second-rate, unlicensed nursing home, it is a necessary and important community resource. New York State law does not require that departments of public welfare "certify" supervised boarding homes to the State Department of Social Welfare in order to be eligible for reimbursement for care of public recipients in them. Until and unless adequate nursing home facilities are available to all of the people it would seem unwise to encourage the development of supervised boarding homes. This viewpoint takes into account the fact that the passing of time has a significant effect on the needs of all people, especially older persons. Unless it is possible to remove persons from supervised boarding homes to nursing homes (and to hospitals and medical domiciliary care facilities) whenever they need the latter type of care and, conversely, to remove persons from nursing homes to boarding homes whenever the need is for only shelter and board under supervision, neither type of facility can be used effectively and economically.

Public health workers generally need to review critically their administrative practices in the light of the extent and special character of the needs of older persons.

Improvement and extension of nursing home and related medical care facilities are urgent needs in a nationwide, integrated approach to the

medical-social problems of all older persons.

Licensure of all private and publicly operated "between the hospital and home" facilities by the state department of health is administratively practicable and desirable.

Education should keynote the administration of a licensure law. Supervision should be inclusive and cover medical, preventive, health, and social services.

Corrective legislation is indicated. Care in a public medical facility should be a reimbursable item of expense to local government.

Care in a public institution should be available to all who need it. Payment for such services should be required according to ability to pay. Both privately and publicly operated medical care facilities should provide quality services geared to the needs of older persons.

In the opinion of the writer, the

American Public Health Association should add to its existing committee structure one on sheltered care for older persons.

Problems of an Aging Population*

Preventive Aspects of Cancer Control

HERBERT L. LOMBARD, M.D., M.P.H., F.A.P.H.A.

Director, Division of Cancer and Other Chronic Diseases, State Department of Public Health, Boston, Mass.

OVER thirty years ago the first cancer control measures in the United States were inaugurated. Starting as a project of a few individuals, the movement has expanded until, at the present time, its recognition as a public health problem is indisputable. This third of a century has witnessed an increasing interest in the cancer problem, a better knowledge of the disease, and a decline in the female age adjusted death rate. At this time it seems pertinent to review the accomplishments of this period inasmuch as cancer control is entering an era of expanding activity caused by an accumulation of events; namely, the closing of the war, grants-in-aid to states of funds identified by Congress for cancer control, the intensive drive of the American Cancer Society, and the interest in the atomic discoveries and their relation to cancer, together with the popular belief that, given sufficient funds, science can conquer even cancer. This review of progress in cancer control depicts accomplishments from which certain patterns for future guidance have emerged.

RESEARCH

Thirty years ago chronic irritation was considered the major factor in carcinogenesis. The earlier works on heredity in animals had appeared, and two Japanese scientists had just proved that cancer could be produced by the

products of combustion of coal. It was known that the incidence of cancer increased with age, that it could occur in any part of the body, and had certain geographical predilections, such as the rarity of breast cancer in Japan, and the high incidence of stomach cancer in Switzerland.

Since 1915 fundamental research has expanded along the lines of genetics, hormones, biophysics, carcinogenic chemicals, cell growth, and viruses. Knowledge today is far in excess of that in 1915, but extensive study is still required. With the expanding research programs of the U. S. Public Health Service, the American Cancer Society, and other organizations, knowledge regarding the disease will continue to increase, and there is a strong probability that improved means of prevention will be discovered.

CANCER CLINICS

The facilities for diagnosis and treatment of cancer have been extended and their utilization has been increased. Three hundred ninety-two cancer clinics were approved by the American College of Surgeons in 1945. This is far short of the number proposed by the National Advisory Cancer Council, one for every 50,000 individuals, but is a great improvement over the few clinics at the beginning of the century. Approval by the American College of Surgeons entails clinical facilities, including radiation, social service, and an adequate record system. The staff should include representatives of all the hospital

* Presented before the Health Officers Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 14, 1946.

departments concerned with the diagnosis and treatment of cancer, and should meet for regular conferences on individual cases. Clinics that merely diagnose and treat patients are neglecting a major service to the profession, namely, that of making available the great wealth of data which should be collected and utilized. Many clinics fail to do this because they lack personnel trained in the collection and analysis of data.

One of the recent innovations of cancer service is a clinic intended to furnish physical examinations for well individuals. There has been considerable discussion regarding the name of this type of clinic. It has been called the prevention clinic, the detection clinic, and the case finding clinic. None of these seem to describe exactly the service offered. The discovery of precancerous lesions is a preventive service. The detection of early cancer among symptomless individuals might be classified as either detection or case finding, but so also could be the finding of early cancer among individuals who present symptoms. Moreover, reports of the prevention clinics indicate that many of their patients have definite symptoms. Such patients should go to a diagnostic, rather than a prevention clinic.

Over the years some of the Massachusetts clinics have functioned like prevention clinics, with the exception that no effort was made to have symptomless persons attend. About a third of the patients have cancer, a sixth benign tumors or precancerous lesions, and a twentieth have no pathology. The remainder, comprising the large bulk of individuals attending the clinics, have non-malignant conditions. The small percentage of individuals with no pathology is probably due to the fact that about 85 per cent of all clinic patients have been referred by their family physicians. This Massachusetts experience suggests one method of furnish-

ing prevention clinic service by broadening the scope of the present diagnostic clinics.

CANCER CONTROL PROGRAMS

The cancer clinic is but one part of an integrated cancer control program. Other activities include statistical research, education, hospitalization, and the diagnosis of pathological tissue.

Twenty-three years ago Dr. Eugene R. Kelley presented a paper before this Association in which he pointed out the following requirements of cancer programs:

1. The great need of discussion and study by health department administrators to determine just what their proper niche is in the cancer struggle.

2. The need of better statistical data as to the present facts and the need of additional personnel and funds for health administrators adequately to collect, collate, analyze, and diffuse these facts.

3. The need of more extended facilities for early diagnosis and of stimulating the professions to utilize fully these facilities when established.

4. The need of better hospital facilities for the inoperable group of cancer victims.

5. The supreme and pressing need of new and efficient methods of both arousing and retaining public interest in and understanding of the significance of cancer whereby a large degree of success may be reasonably anticipated even with our present faulty weapons for combating the menace of malignancy.¹

At that time there were no state cancer control programs. Today nearly half the states have programs, but the needs which Dr. Kelley discussed are still not met.

The ideal of any cancer control program is the prevention of the occurrence of the disease, but unfortunately the number of cases that can be prevented by active measures is limited. This is due in part to a lack of scientific knowledge and in part to a lack of public receptiveness to known facts. While there is an association between cancer and both physical and chemical carcinogenic agents, it is difficult to induce in-

dividuals to accept and apply this knowledge. For instance, it would be impossible to convince everyone to avoid tobacco or to be protected from the actinic rays of the sun by wearing veils. Also, while the removal of all moles would doubtless prevent a certain number of cancers, the health officer would be loath to advocate a wholesale removal of them when he realizes that nearly every person has one or more and that only a small percentage of moles ever become cancerous.

Even if campaigns against chronic irritations and precancerous lesions were far more effective than they are at present, the number of cancers that could be prevented by such endeavors would be relatively small. There is, however, the probability that certain cancers can be prevented in an indirect manner. In the *Decennial Supplement of the Registrar-General of England and Wales* it was shown that a group of cancers including those of the skin, mouth, uterus, esophagus, larynx, and stomach were more prevalent among the poor than among the rich.² It was felt that if the economic level could be raised the cancer rates of these sites would be lowered. Massachusetts figures show some confirmation of this hypothesis.

In recent years, coincidental with a rise in the standard of living, this group of diseases has shown a downward trend, and the individual diseases composing the group have shown either a downward trend or no trend.³ Prevention by improving the standards of living could not be considered the result of planned effort on the part of either the health officer or the individual, but would be an indirect or a passive method of prevention.

At the present time, however, the administrator of a cancer control program concentrates his major efforts on the prevention of death rather than on the prevention of the disease. This resolves itself into early recognition and ade-

quate treatment, and requires prompt action on the part of both patient and physician. The patient should consult a physician as soon as symptoms are noted. The physician should recognize the condition without delay, and unless he is skilled in the treatment of malignant tumors he should seek consultation or refer the patient to a special clinic. Thus with our present state of knowledge an effective cancer control program must depend largely on early diagnosis and adequate therapy.

With the increase in the number of states inaugurating cancer programs it has become apparent that different methods of attack are necessary. A populous community on the east coast will need an entirely different technique from that applicable in a rural community in the midwest. Moreover, the special interest of the administrators is a factor in the choice of a program. Nurses and social workers are particularly interested in the facilities for care of patients, and their contact with the advanced cancer patient spurs their humanitarian instincts. The physician is primarily interested in the clinical aspects of the disease, but even in this profession the different specialties alter the point of view. The surgeon, the radiologist, the pathologist, the general practitioner, all have different ideas regarding the best method of approach to the cancer problem, while public health officials have a still different point of view. Fortunately, a considerable amount of originality has been used in conducting the cancer programs in the different states. New York places particular emphasis on reporting of cancer; Connecticut specializes in a cancer registry; Missouri has built its program around the Ellis Fischel State Cancer Hospital; West Virginia has reached into its most rural communities with its cancer services; while Massachusetts has devoted especial attention to statistical research.

EDUCATION

The beginnings of cancer education may be said to have occurred when a committee of the American Medical Association in 1905 reported in favor of educational work in cancer, and as a result various pamphlets on cancer control were published.⁴ In 1909 the Cancer Commission of the Medical Society of Pennsylvania was organized and its report in the following year focused attention on delay in receiving cancer therapy.⁵ The Clinical Congress of Surgeons of North America appointed a cancer committee which in 1912 secured the publication of popular articles on cancer in several widely read magazines.⁴ In 1913 the American Society for the Control of Cancer was organized, and from that time to the present has had great influence in the cancer control movement.⁴

The objective of cancer education is the dissemination of sufficient information to generate action if necessary. Education has been conducted by federal, state, and local official organizations, the American Cancer Society, and the medical profession. Professional education has been offered through the medical schools, medical societies, free distribution of books and periodicals to physicians, graduate courses, cured cancer clinics, and teaching clinics. Lay education has consisted of magazine and newspaper articles, public addresses, radio presentations, motion pictures, lantern slides, posters, pamphlets, bulletins, and various exhibit material.

In Massachusetts an educational program based largely on talks by local physicians has been in operation for over ten years. Recently these have been augmented by institutes for the interchange of committee ideas regarding cancer education, school programs as an indirect method of parent education, and house-to-house surveys as an evaluative measure of present knowledge and an opportunity to impart further infor-

mation. Many years ago Dr. Bloodgood stated that cancer lectures, especially to women, are the best means of educating the public.⁴ A survey of some ten cities in Massachusetts has confirmed the value of this type of education. Next in importance to the spoken word in educational value was the written word, while only a few individuals mentioned visual aids as a source of knowledge. It seems apparent that visual aids have not been particularly important in cancer education in Massachusetts, either because of poor choice of material, insufficient use, or because their intrinsic value is negligible.⁶

OCCUPATIONAL CANCER

Considerable knowledge has accumulated regarding cancer in industry. It is known that some industrial cancers may be prevented by the use of building materials which prohibit the absorption of carcinogenic substances, and by the utilization of safety devices to protect the workers, but such installations depend upon the foresight of the management rather than upon the initiative of the individual. Hueper has stated:

Whenever the managers of new plants and their medical advisers have neglected to profit, in the construction and operation of their establishments, from the adverse experiences previously had by other manufacturers in the same fields, there has appeared some ten to fifteen years later a renewed, acute and sometimes epidemic-like occurrence of occupational cancers in these industries. . . . Although today a great deal of evidence on the causes of occupational cancer and the conditions under which it develops is available, relatively little effort has been made to spread this knowledge among parties who are vitally concerned with this information, namely the managers and physicians of industrial concerns, although they carry the main load of controlling this preventable type of cancer. This situation is the more deplorable because the present rapid development of industry tends to extend the hazards of the known industrial carcinogenic agents while at the same time creating new ones which may cause the appearance of cancers ten to twenty years hence, unless concerted efforts are made in time to discover

and control such dangers by appropriate countermeasures.⁷

PATHOLOGICAL SERVICE

The rise in tissue diagnosis service deserves mention. Pathological service in hospitals has greatly increased and many states are furnishing tissue diagnosis service to physicians. It is felt that the diagnosis of specimens submitted to the laboratories, while of immediate concern, is only one aspect of the function of the tumor diagnosis service, since the material submitted can be used also for histologic and statistical studies.

In Massachusetts a grant from the Commonwealth Fund has made possible a three year study to determine the possibility of including in the service furnished by the pathological laboratory the examination of vaginal smears for diagnosis of uterine cancer by means of the Papanicolaou and Traut technique. Preliminary findings indicate that perhaps one out of every four hundred women with no gynecological symptoms has uterine cancer, while a much larger percentage of those with gynecological symptoms are found to have cancer of that organ.

HOSPITALIZATION

Only a few states have included cancer hospitals in their control programs, but even in these states the greater part of the cancer load is carried by other hospitals. In Massachusetts less than 5 per cent of cancer cases are cared for in the two state cancer hospitals. The trend of expansion in service is largely at the local hospital level, not only for the cancers that offer hope of cure, but also for the far advanced cases.

While the present trends indicate that there will not be many state cancer hospitals established, and that adequate service for the patient can be maintained through local institutions, it is

pertinent to point out one outgrowth of the cancer hospital program in Massachusetts. During the 19 years in which Pondville Hospital has operated, 118 doctors have been graduated after one to two years' residency. These men had all interned in other institutions before coming to Pondville and at the conclusion of their stay at Pondville were not only proficient in the diagnosis and treatment of cancer but were, for the most part, interested in the entire control program. Nearly half of them have opened offices in Massachusetts communities and the remainder in nineteen other states and four foreign countries. This infiltration of trained cancer personnel augurs well for better cancer service.

STATISTICAL RESEARCH

Statistical research has greatly augmented cancer control programs. Data for study have been collected from death records, hospital records, clinic records, morbidity reports, surveys, and questionnaires. Three main types of study have been made: one dealing with causation of the disease, a second dealing with program management, and a third with evaluation of a program. An example of the first is found in Levin's study of the association between syphilis and cancer of the uterus⁸; an example of the second is Macdonald's work on the cancer registry⁹; while an example of the third is the Massachusetts figures which show that a considerable reduction has taken place in the period of delay between first recognizable symptoms and treatment of the disease.¹⁰ Statistical research, which has already done much, will undoubtedly play a leading part in the ultimate prevention of cancer.

ACCOMPLISHMENTS

Certain measurements of accomplishment are available. The decrease in delay, just referred to, is but one of many. These include such diverse items as in-

creasing attendance at cancer clinics and hospitals, the willingness of the public to listen to cancer lectures, the increasing number of magazine articles on cancer, the large number of individuals willing to work for cancer control, and the rapidity with which new state programs have been organized. Probably the most important measurement is obtained in the changing death rate. In the early part of the century the adjusted cancer death rates for both sexes were rising about 2 per cent per year in both the Registration Area of 1900 and Massachusetts. Shortly before this country entered the First World War the increase among females lessened, somewhat more in Massachusetts than in the Registration Area. A change occurred in males around 1926 for both Massachusetts and the Registration Area. From then on the annual percentage increase was only about one-half its previous value. In the middle 30's, a downward trend was noted in Massachusetts among females and a few years later a similar drop occurred in the Registration Area of 1900. Due to the aging of the population the crude rate for both sexes is still increasing. The change in the adjusted cancer death rate offers thought for speculation as to what part of it may be attributed to cancer control activities and what part to other causes.

FUTURE CANCER CONTROL

The basic plan for future cancer control is apparent, and will include expanding clinics, hospital facilities, pathological service, statistical research, and education. The extent of these services and the proportionate effort placed on each is not so clear; and probably geographical location, customs of the people, available finances, and the *particular interests of the local administrator* will determine this. I feel very sure that progress will be made in many parts of the country. In Massachusetts

our immediate plan for improvement includes several items.

1. We expect to open at least one prevention clinic, and from the experience with this clinic determine the need for others. We are anticipating the possibility of extending the function of our present diagnostic clinics to include a greater number of examinations of symptom-free patients.

2. The results of the vaginal smear study will determine the desirability of extending this service to all physicians.

3. The American Cancer Society is financing a study to determine whether or not certain *habits which cause irritation are associated with cancer*. This study is a continuation of an earlier one financed by the Rockefeller Foundation.

4. It is expected that several more schools will adopt programs of cancer education this year. The extension of school programs will be greatly facilitated by the action of the Committee on Health Problems in Education of the National Education Association and the American Medical Association which has recommended that instruction concerning the nature of cancer, and the known methods of prevention and control, be included in the course of study in high schools.

5. Arrangements are being made to conduct a state-wide survey to obtain pertinent data regarding the disease, somewhat similar to the previous survey conducted in Massachusetts in 1929-1931.

In this brief resumé of a third of a century of cancer control, it seems fitting to pay tribute to those leaders of this movement who are no longer with us but whose efforts have blazed the way for others to follow.

Dr. Joseph Bloodgood—Pioneer in cancer education and surgical pathology

Dr. William Duane—Physicist

Dr. James Ewing—International authority on tumors

Dr. Ellis Fischel—Prime figure in cancer control movement in Missouri

Dr. Jonathan M. Wainwright—Outstanding advocate of cancer control

Dr. H. Gideon Wells—Geneticist in cancer

The following men were from Massachusetts, and because of my close association with many of them I may be too much impressed, but I believe their contributions to be real.

Dr. George H. Bigelow—President of the American Society for the Control of Cancer; organizer and administrator of the Massachusetts Cancer Program

Dr. Walter B. Cannon—Investigator of gastrointestinal physiology by use of the x-ray

Dr. Robert B. Greenough—An outstanding contributor of time, example, and personal effort in the cause of cancer and a proponent of cancer clinics as President of the American College of Surgeons, President of the American Society for the Control of Cancer, and President of the Massachusetts Medical Society

Dr. Frederick L. Hoffman—Pioneer in the collection of cancer statistics

Msgr. Ambrose F. Roche—Background figure in the establishment of the Massachusetts Cancer Program

Dr. John Collins Warren—Organizer of the Harvard Cancer Commission

In closing, it seems pertinent to quote from another cancer pioneer, the late Dr. J. W. Schereschewsky of the United States Public Health Service:

That the cancer death rate will continue to increase in the future as it has in the past is not to be supposed. Physical, chemical, and biologic processes all tend to a state of equilibrium. So in the case of cancer, when the forces which are tending to raise the human race to a new and higher level of susceptibility have spent themselves, we may expect no further increase in the rate, at least from the operation of these causes, and, lying

concealed in these evils, as in Pandora's box, there is still the hope in the hearts of the medical profession and of the students of the public health that tomorrow, next month, or next year the true defense against this relentless foe will be vouchsafed to us.¹¹

Problems of an Aging Population*

Public Health Aspects of Diabetes

HUGH L. C. WILKERSON, M.D., M.P.H.

Surgeon, U. S. Public Health Service, Boston, Mass.

DIABETES is a major public health problem which is increasing in importance. It has rapidly advanced in rank as a cause of death from twenty-fifth place in 1900 to ninth place in 1940.

When one considers the public concern about such diseases as tuberculosis, cancer, and anterior poliomyelitis, diabetes appears as a relatively neglected disease. Probably to a greater extent than cancer or heart disease, diabetes is amenable to definite methods of control by using the presently accepted knowledge of its cause, diagnosis, treatment, and complications. There is a growing recognition of the challenge this problem presents for organized community effort: to identify early cases; to attempt to prevent the disease, particularly among those susceptible by heredity and by obesity; to prolong the lives of diabetic patients; and to lessen the national economic burden produced by its complications. The situation calls for concerted action.

In 1924 Haven Emerson¹ pointed out that diabetes incidence and mortality had increased more rapidly than the incidence and mortality of any other recorded disease for the preceding 50 years. The United States Bureau of the Census² has reported that among the causes of death which showed an up-

ward trend from 1921 to 1940, diabetes ranked second. Statistics indicate that great progress has been made in reducing the death rate from many other causes since 1900, particularly the infectious diseases, among which only tuberculosis, pneumonia, and influenza stand above diabetes. Figure 1 shows those causes responsible for a larger number of deaths than diabetes in 1940 in the United States.

In eleven states diabetes is responsible for more deaths than is tuberculosis; for the country as a whole, it causes one-third more deaths among white women than does tuberculosis. These comparative figures illustrate the need for an active program to prevent and control diabetes.

The need for informing the public about the problem of diabetes appears unusually great when we consider that for the conservatively estimated 660,000 cases, according to Dublin³ of the Metropolitan Life Insurance Company, voluntary health agencies collect only \$30,000 a year, or 5 cents a case, as contrasted with the excellent public response to tuberculosis control, for which it is said voluntary agencies alone collect annually \$15,000,000, or \$22 a case.

Figure 2 shows the proportion of total mortality caused by diabetes. In 1920 diabetes was responsible for 1.2 per cent of all deaths; by 1940 this proportion had risen to 2.5 per cent. The age group at which diabetes is charged with

* Presented before the Health Officers Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 14, 1946.

FIGURE 1

THESE CAUSES WERE RESPONSIBLE FOR A LARGER NUMBER OF DEATHS THAN DIABETES IN 1940 IN THE UNITED STATES

SOURCE: Vital Statistics Rates in U.S., 1900-1940. Table 15 U.S. Bureau of the Census

FIGURE 2

PROPORTION OF TOTAL MORTALITY CAUSED BY DIABETES

Based on mortality statistics published by U.S. Bureau of the Census

the largest proportion of deaths is that between 55 and 74 years. In 1940 the disease was reported as responsible for 3.9 per cent of total mortality in this age group.

Diabetes death rates show an upward trend for both men and women, white and non-white, for the period 1920 to 1940 (see Figure 3). Adjustment for age on the basis of the population in 1940 reduces the rates of increase, but does not account for the increase in the period. The greatest per cent increase in age-adjusted rates has occurred in the case of non-white women—from 14.4 to 36.8 per 100,000—an increase of 155.6 per cent. For white females the corresponding increase was from 18.8 to 34.8 per 100,000, an increase of 52.6 per cent. The increases among men are less than those noted among women; the smallest rise is 19.6 per cent for white men when adjusted for age.

In forming a concept of the actual mortality among diabetics it should be remembered that mortality statistics are not wholly reliable, partly because insulin treatment allows the underlying diabetes to be overshadowed by other causes of death in the Census reporting. This tendency will become even more pronounced as deaths from diabetic complications are reduced further. For example, investigation by Joslin and Lombard of 744 diabetic patients previously treated by Joslin disclosed that only 62.9 per cent were classified as diabetic on the death records.⁵ These findings having been confirmed it is concluded, therefore, mortality figures are inadequate in showing the number of deaths among diabetics.

To bring about the consummation of a plan of control there must be a greater realization of the prevalence of diabetes by the public and by the medical profession. There must be a wide acquaint-

FIGURE 3

DEATH RATES FOR DIABETES SHOW INCREASES FOR ALL RACES AND BOTH SEXES FOR THE PERIOD 1920-1940

ance with the important facts concerning the incidence of the disease and its distribution by age, sex, race, marital status, and occupation, as well as a knowledge of its socio-economic importance. Such information is indispensable in organizing a community's resources for control of the disease.

INCIDENCE

Diabetes is not a reportable disease and, therefore, its incidence is not accurately known. The number of people who have the disease in the United States today has been estimated as 660,000 on the basis of the National Health Survey made by the U. S. Public Health Service in 1935-1936,⁴ which survey was directed only toward finding the number of known cases in a given number of people. Other estimates of the number of cases today exceed one million.⁵ According to the findings of the National Health Survey, the number of men with diabetes was 2.7 per 1,000; the number of women, 4.5 per 1,000. It has been estimated that if the prevalence rates discovered in the survey prevailed in the general population during 1940, over one-quarter of the total diabetics were under 50 years of age, one-quarter between 50 and 60, and a little less than half were at the age of 60 and over. The average age of male diabetics was 55.6 years, and that of females, 56.7 years.⁶

More recent investigations based upon findings of physical examinations involving urinalysis reveal an incidence of diabetes higher than that which might be expected according to the National Health Survey.

Physical examinations at local Selective Service Boards and Induction Stations from April, 1942, to December, 1943, disclosed that the prevalence of diabetes among registrants was 2.6 per 1,000 examined—more than twice as high as that recorded in the National Health Survey for men of approximately

the same age group. The rate of overweight recorded for Selective Service registrants was high, and this is significant in the problem of diabetes, because clinical statistics demonstrate that an overweight person with diabetic ancestors is a likely candidate for diabetes.

The Federal Security Agency made a study of the health records of 150,000 NYA youth examined in 1941, boys and girls from 16 to 24 years of age.⁷ It is noteworthy that the NYA included only the low income group, because there is some contention that diabetes incidence rates are low in that group. However, the diabetes prevalence among NYA youth aged 16 to 24 was found to be 1.2 per 1,000—while the National Health Survey recorded a rate of only 0.59 cases per 1,000 persons aged 15 to 24.

In a survey in Arizona, where there was a very low recorded mortality rate of diabetes, Joslin found a prevalence of diabetes comparable to that of the National Health Survey.⁸ Of like significance to public health and preventive medicine is the fact that 78 per cent of newly discovered diabetics in a study at the Boston Armed Forces Induction Station had no knowledge of their condition.⁹ Wherever investigations have been made by means of physical or laboratory examinations, a prevalence of diabetes has been discovered significantly higher than that recorded in the National Health Survey. This is strong evidence in favor of organized case finding programs to discover unknown cases of diabetes by means of urine and blood tests for sugar.

A demonstration case finding program has begun in Oxford, Mass., a typical semi-rural New England town of about 5,000 cosmopolitan population, in October, 1946, by the U. S. Public Health Service Diabetes Demonstration Unit. The object is not only to obtain valuable epidemiological data, but also to

provide a pilot study for diabetes case finding. The proposal to attempt finding all the mild and undetected diabetics in the town and placing them in the care of their physicians was first discussed with state and local health and medical groups, and then presented to the civic leaders of the town. Interest in the program has steadily mounted, and co-operation of the social and civic groups in the endeavor has been outstanding. The school children, guided by the school and district health nurses, have responded well by bringing requests for the tests from their parents. Public health personnel carrying on the work of the survey consists of a public health officer, technicians, health educator, a clerical staff, and coöperating local and district health nurses. Identifying data including age, sex, color, nationality, weight, height, and history of diabetes, as well as the results of blood and urine analyses for sugar, are being recorded for each individual. Abnormal laboratory findings will be rechecked carefully with glucose tolerance tests and the patients referred when indicated to their doctors, who will receive a copy of the laboratory findings. In so far as possible, collection of blood and urine specimens is timed to follow an average full meal. In this way very few mild diabetics would be missed, and the screening will be more complete.

Whether we have a truly increased incidence of diabetes, or whether the advancing age of the population and increased duration of the disease produce a cumulative effect, it is expected that the number of diabetics in the United States will increase by 18 per cent from 1940 to 1950, while the total population may grow by only 9 per cent. By similar deductions, our total population about 1985 will reach a maximum, which will be 22 per cent greater than it was in 1940; however, in the same interval of time the number of diabetics may increase by 74 per cent.⁶

AGE OF ONSET

Barach's¹⁰ analysis of the age at onset of 1,000 cases of diabetes shows that, while the disease makes its appearance at all ages, the onset is most commonly between the ages of 50 and 55 (sixth decade). Joslin⁵ also shows the maximum susceptibility is in the sixth decade for both males and females. The considerable incidence of the disease in childhood, adolescence, and early adult life, as well as the declining susceptibility in the later decades, indicates that diabetes should not be called a disease of old age.

SEX

Sex appears to be a determining factor in diabetes incidence and mortality, because an excess mortality in women as compared with men is characteristic. Up to the age of 35, female mortality rates are about the same as those for men, but after age 45 there begins an appreciable excess in the female rates. The maximum proportionate difference occurs at ages 55 to 64.

RACE

It is proverbial that diabetes is more prevalent among Jews than among Gentiles. More recently, however, data have shown an unusually high incidence among the Irish. At one time Negroes appeared to have very little diabetes, but today the mortality among the whites is only a little higher than among the Negroes when rates are adjusted for age.

MARITAL STATUS

Figure 4 shows the death rate per 100,000 persons for diabetes by sex and marital status in the United States in 1940. Age adjusted death rates on the basis of marital status indicate that the highest mortality occurs among married women and those who have been married. The rate for married women is nearly twice that for single women, and

nearly twice that for married men. The death rates for widowed and divorced women are still higher. On the other hand, the diabetes death rate for married men is the lowest of the marital group compared with rates for single, widowed, and divorced men.

Joslin⁵ attributes the higher death rates for married women primarily to over-feeding and under-exercise during and after pregnancy, resulting in overweight. Among a group of married women examined with onset of diabetes after 45, the average weight was 180 pounds as

FIGURE 4

DEATH RATES PER 100,000 PERSONS FOR DIABETES BY SEX AND MARITAL STATUS: UNITED STATES, 1940

* Obtained by applying age-sex-specific death rates for the marital class to the population of the U.S., 20 to 74 years of age in 1940*

SOURCE: Deaths from Selected Causes by Marital Status, by Age and Sex, United States, 1940, Vol. 23, No. 7; U.S. Bureau of the Census

compared to only 160 pounds for a group of single women.

OCCUPATION

It seems the occupational and economic status of an individual affects his chances of becoming diabetic only inasmuch as it results in lessened physical activity, overindulgence in food, and conditions that favor obesity. Almost all authorities accept the rule that liability to diabetes increases in proportion to the degree a person is overweight.

POPULATION SIZE

Comparison of diabetes death rates on the basis of population-size groups demonstrates the predominance of diabetes in large cities in contrast to rural areas.

SOCIO-ECONOMIC IMPLICATIONS OF THE DISEASE

If there are 660,000 or more diabetic persons in the country, as reported in the *National Health Survey*, their employment status is of concern to the taxpayers of the nation as well as to the families of the diabetics. Statistics are not complete on this subject, but some indications of the problem were discovered in the *National Health Survey*. About 34,300 diabetics were classified as permanently disabled, on the basis of having been impaired for 12 months prior to the canvass. There were estimated to be about 1,500,000 permanent invalids in the United States. Only five chronic diseases were responsible for more invalids than diabetes, and only ten diseases were responsible for more working days lost. This time lost from work may be considered an index of economic loss. Preventive and educational programs should reach these diabetics and help to salvage those who could become self-sustaining.

Mosenthal¹¹ has commented on the difficulties which a diabetic often en-

counters in seeking employment in industry, and the common objections to hiring one, such as loss of time from work, insulin shock, occurrence of complications, and vulnerability to traumatic injuries. He believes modern methods of treatment should alleviate most of these difficulties "so that in all probability, the well treated diabetic may qualify on a par with normal persons with regard to longevity and fitness to work in many occupations."

Gates¹² reported a comparatively high incidence of diabetes among employees of a large industry. All employees were given an annual physical examination, including urinalysis. A selected group of 109 individuals believed most likely to have diabetes on the basis of family history or sugar in the urine were given glucose tolerance tests. As a result of the tests, 17 were classified as diabetics (in addition to 3 known diabetics); and 19 persons were classified as "potential diabetics." The newly discovered diabetics will have their period of usefulness to industry extended and they will be able to prolong their lives.

PREDISPOSING AND PRECIPITATING FACTORS

In consideration of the causes of diabetes, numerous authorities have presented significant evidence that heredity and obesity are outstanding. Evidence is accumulating that the disease is handed down through generations as a recessive Mendelian characteristic. The accepted theory of heredity in diabetes indicates that every child is born with or without a diabetic hereditary predisposition, and as the hereditary trait is recessive, the disease may skip a generation. Numbers of people predisposed can go through life without developing the disease in its clinical form, either because they do not live to the age at which it develops to the stage of presenting clinically recognizable symptoms,

or because by chance or good care they avoid precipitating causes, such as obesity.

The hereditary tendency in diabetes was noted as far back as the 7th century A.D., and has been considered paramount as a cause by many authorities. Joslin cites evidence of a family history of diabetes in 55 per cent of a group with diabetes of 20 years' duration with onset in childhood. In his oldest age group, 75 years and over, it is 29 per cent. In a group of childhood cases of Jewish parentage, a family history of diabetes was cited in 49 per cent. Blotner and Hyde,⁹ in their studies of selectees found a family history of diabetes in 32 per cent of one diabetic group and 43 per cent in another.

Not all fat people become diabetic, but in a person who is susceptible to diabetes, obesity may be the exciting factor precipitating the disease. Studies have shown that diabetes is as much as 8 times as common among persons who are more than 25 per cent overweight as among those of average weight, and less common among those who are average or under the average weight, as measured by standard height-weight-age scales. Barach¹⁰ found in a series of 1,030 diabetics of all ages that 90 per cent had at one time or another in their lives gone through a period when they were obese. Joslin says that from the fourth decade on, 80-90 per cent of diabetics have been overweight on or prior to onset of their disease.⁵

There is a difference of opinion regarding infection as a cause of diabetes, but it is generally agreed that infection may aggravate a latent diabetic state or, as Lukens¹¹ has said, "act as nature's sugar tolerance test."

There seems to be no good evidence that excess of carbohydrate, protein, or fat, per se, in the diet favors the development of diabetes. It does appear fairly well established that overin-

dulgence in terms of total calories may lead to obesity and therefore predispose to diabetes.

DIAGNOSIS

The symptoms of diabetes may bring a person to his physician with a suspicion that he has the disease. The cardinal symptoms of unusual thirst, excessive urination, increased hunger, loss of weight, fatigue, and pruritus should become more generally and better known, so that persons affected would seek medical attention at the onset of these symptoms. Other complaints which often arouse a suspicion of the attending physician are vague neuritic or cramplike pains in the legs, infections slow to heal, frequent boils and carbuncles, extensive pyorrhea, and unexplained impaired vision.

The onset of diabetes is insidious. Except among children it is rarely defined with any degree of accuracy. Our knowledge of the physiological events which take place during the latent stage is very meager. The education of the public, therefore, should stress the importance of routine or regular urinalyses, particularly of those who are relatives of diabetics, obese, and over 45 years of age.

At present the diagnosis of diabetes rests upon the urine and blood tests for sugar. A urinalysis in diabetes is as important as an x-ray in pulmonary tuberculosis. It must be stressed, however, that a diagnosis is not made by a test of the urine alone. There are many people with glycosuria, usually slight in degree, who do not have, nor ever will have diabetes, and it is neither just nor profitable to physician, patient, or public to impose a diagnosis of diabetes unless the disease exists. Sugar found in the urine should be considered as a demand for a thorough check of the blood to prove whether the condition is or is not diabetes. Too often it is mistakenly thought that a little glycosuria

means too great an intake of sweets and, consequently, an early diabetes gradually becomes advanced and finally severe complications force emergency treatment—perhaps too late. For the sake of safety, glycosuria means diabetes until proved otherwise. A blood sugar estimation, however, must be done to make the diagnosis, and once the diagnosis is established, treatment should be prompt and aggressive.

Standards and facilities for diagnosis have improved so that patients can be told that 4 drops of urine and one drop of blood are sufficient specimen material for diagnostic laboratory procedures. Further interchange of ideas will yield more standardization and improvement.

PREVENTION AND CONTROL

Before the advent of insulin treatment the average life of a diabetic child was less than 2 years. Now only a few children die of diabetes. Young adults live 4 times as long, and persons over 60 years live twice as long as formerly. From the public health standpoint, the big problem is how much damage is done to vital structures by an unrecognized, prolonged mild diabetic state before frank symptoms develop which bring patients to their physicians for treatment.

Scott¹⁴ has said that if and when all the means of prevention and treatment now known are applied, diabetics will no longer die of diabetes. While medical science has not unraveled all the things we need to know, we do know the facts about the disease that make it amenable to control. We have the instruments with which to work, and a vast amount of knowledge awaits a widespread application.

Failure of the diabetic patient to control his disease is too often due to ignorance of the true nature of the disease and its complications. It must be told again and again to all known diabetics that the span of life and freedom

from complications is dependent upon the patient's utilization of a full and complete understanding of his disease and his adherence to a practical regime of proper diet, prescribed insulin, regulated exercise, and general hygiene.

The family physician sees and treats more diabetics than the specialist, and he thus has a great responsibility. With extensive case finding programs, more early diabetics who are symptomless will place themselves under the care of their family doctors. Among the requirements of effective therapy in diabetes is the indispensable implement—the *sine qua non* of diabetic therapy—the willingness of the physician to dedicate a considerable amount of his own time to full and complete instruction of his patient in the details of self-management of his diabetes, or his coöperation in arranging for instruction and education of his patient by other competent and specially trained professional personnel. There is no effective system of therapy which eliminates the education of the patient.

All hospitals should be equipped and prepared to handle the diabetic emergencies of coma and insulin reactions. For this there will need to be laboratory service available at all hours. Greater still is the need for hospitals for ambulatory patients—new diabetics—where they may live for a week or ten days with other diabetics and learn through lectures, demonstration, study, and practice the fundamentals of the management of the disease. Summer camps for diabetic children should be established in all states as a means of formulating habits of work and play peculiar to a diabetic child, and of utmost importance in a program to improve their well-being and prolong their lives.

The diet to which a diabetic will usually adhere if he understands the reason must be adequate for his needs, palatable, and psychologically accept-

able. In the doctor's office, hospitals, or clinical centers, the dietitian, nutritionist, or the nurse thoroughly trained in the dietetics of diabetes is a valuable assistant to the medical practitioner.

Among the preventable complications of diabetes, coma still occurs, but fear of its outcome is to a great extent conquered by insulin. However, it still occurs far too often with too high mortality. With more and wider dissemination to the public of information about diabetes there should be fewer repetitions of the hospitalization of cases of coma before the diagnosis of diabetes is made. Nine such cases were presented at a clinic recently in one of our larger cities.

Insulin shock in the well educated case usually results from carelessness. Prevention of this complication can largely be accomplished through education and repeated instruction of the diabetic patient.

With increased longevity for diabetics as a result of improved treatment, the most devastating complications are the progressive degenerative changes associated with arteriosclerosis affecting the heart, eyes, kidneys, and lower extremities. Impaired vision progressing to blindness, and amputations necessitated by gangrene produce invalidism in an increasing number of diabetics.

Coöperative clinical research is needed because knowledge is lacking as to all the factors responsible for these complications. Early diagnosis may be the important answer.

Blindness is one of the most devastating complications of diabetes. Of 1,176 blind people in Massachusetts receiving over one-half million dollars in state and federal assistance, Reimer¹⁵ found 3.8 per cent with diabetes recorded as the cause of their blindness. During the last 6 months, the Massachusetts Division of the Blind, technically assisted by the Diabetes Demonstration Office of the U. S. Public Health

Service has been carrying out a diabetes case finding and prevalence study among the blind people in Massachusetts. Postprandial urine and blood analyses for sugar among 880 blind persons revealed 5.3 per cent who were known diabetics. Laboratory tests revealed 2.8 per cent more not formerly known to be diabetic. The individuals in this latter group were referred to their family physicians for medical care.

In order to demonstrate the applicability of public health and preventive medicine in diabetes control, the U. S. Public Health Service Diabetes Demonstration Unit will soon provide a group of professional personnel trained in preventive aspects of the disease as a part of the staff of a local health department in two different geographical locations of the country, one in the South and one in the North. These groups will consist of a public health physician, a public health nurse, a health educator, a nutritionist, laboratory technicians, and a clerical staff. They will assist the local health officer in inaugurating and developing a diabetes control program and will coöperate with voluntary agencies interested in diabetes. All plans will be formulated in consultation with an advisory committee from the local medical society.

The basis, therefore, of a preventive program developed in consultation with the local medical society, would be education of the public in regard to prevention of predisposing causes, recognition of symptoms, and realization of the importance of seeking early diagnosis and adequate treatment in order to avoid complications, prolong life, and increase mental and physical well-being.

It is evident that early discovery will lengthen the lives of those who have diabetes, and may prevent development of the disease in potential or borderline cases.

The possible prevention, therefore, of frank or clinical diabetes by early diag-

nosis in the subclinical stage, and especially among the predisposed, will be stressed in the promotion of a case finding program. The public health doctor and his assistants will organize the community so as to obtain local neighborhood and community sponsors of the program. Urine and blood tests for sugar will be offered to all persons in the community, but emphasis will be placed upon the importance of those having the test done who have a family history of diabetes, are female, married, and above normal in weight. All abnormalities in laboratory reports will be sent to physicians designated by the examinee. Those people who have abnormal laboratory findings will be referred to their family physicians.

If the pilot study in Oxford, Mass., reveals the advisability of doing tests on school children in the attempt to discover signs of pre-diabetes or diabetic tendency, then the younger age group will also be considered for case finding surveys.

Education of the patient and his family will consist of offering assistance to the physician in the instruction of his patient in clinical centers, hospitals, or special arrangements at health departments. Patients would be referred to such centers by their physicians. Instruction would be given in the fundamentals of diabetes control, including adjustment of diet, rôle of insulin administration, regulation of exercise, prevention of complications, and simple methods for performing tests for sugar in the urine. Suitable educational media will be used such as films, film strips, food models, posters, pictures, charts, blackboard illustrations, etc. Information is expected to be disseminated to the general public through the usual media of radio talks, press releases, periodicals, pamphlets, posters, and talks, as well as films before organized groups such as churches, civic clubs, etc.

A coöperative plan will be proposed to the medical society to stimulate and promote more graduate courses in diabetes management for physicians, nurses, dietitians, and auxiliary workers in doctors' offices and in hospitals.

In the field of clinical research in diabetes mellitus, it is hoped there will be coöperative endeavor to arrive at standard criteria for diagnosis and basic principles of treatment. Efforts are being made to encourage more clinical research, and one step in this direction is the recent establishment of a Metabolic Diseases Study Section under the Research Grants Division of the National Institute of Health.

A special attempt is being made to simplify methods for doing blood sugar analyses. The physician needs in his office or in his laboratory a simple, relatively inexpensive apparatus with which he himself, his office assistant, his technician, or his nurse, can take a drop of blood from his patient's ear lobe and in five to ten minutes analyze it for sugar content. This would allow the doctor to make a diagnosis of even early symptomless diabetes on the patient's first visit to his office.

Those conducting public health programs have a responsibility for disseminating information to the public about the habits and conditions of life which are conducive to diabetes. Through case finding, public health organizations might assist in bringing the early symptomless diabetic under the care of his physician. The practising physician, the nurse, the dietitian, and the medical auxiliary workers should be well informed about the treatment of the disease. Above all there should be close coöperation between the practising physician, the patient, and the health worker, in order to attain the common goal of diabetes control.

It is hoped that from the experience gained in the demonstrations which are now being developed, a practical diabetes

program will evolve which will be suitable for the average local health department to consider for integration in its general health program.

Confidential System for Filing True Cause of Death

Beginning on January 1, 1947, the New York City Health Department provided New York physicians with a confidential report form for reporting the true cause of death. Heretofore certain causes such as alcoholism, syphilis, mental disease, tuberculosis, and others have not been reported accurately because of the family feelings or because of the Civil Practices Act which requires that physicians shall not be allowed to give out information learned from a patient under treatment.

Under the new system, two forms will be provided, one for the family which will list the cause of death as from natural causes; the other used in privacy by the doctor will list the true cause. The new system was put into operation after an 8 year trial in the Borough of Manhattan, under the direction of the late Thomas J. Duffield, long-time Director of Research and Sta-

tistics in the department. Its effect upon the vital statistics of the city was immediately noted. In 1939 syphilis deaths increased 35 per cent over 1938, paresis and locomotor ataxia each jumped 16 per cent. Brooklyn Borough had much lower figures for these causes of death, with correspondingly higher percentages of heart and brain maladies.

The new plan was made with the coöperation and approval of the New York Academy of Medicine, the five county medical societies of the city, and the undertakers. In announcing the change, Health Commissioner Weinstein pointed out that public health officers virtually everywhere have known that physicians often withheld the true cause of death, thus introducing inaccuracies into mortality statistics of every country. The one exception is Switzerland which has had a confidential report form since 1926.

Recent Studies on Disinfection of Air in Military Establishments*

IN confined spaces occupied by persons, breathing and rebreathing a common air supply, there exists a potential hazard of respiratory infection from air-borne pathogenic bacteria and viruses. One of the objectives of sanitary ventilation is to reduce the risk so far as may be practical without interfering unduly with normal activities, and with due regard for economy. The risk arises from the fact that the environment may become contaminated with microorganisms from infected persons. Some of these organisms may gain access to the respiratory tract of susceptible individuals, giving rise to new infections. The process of removing or inactivating air-borne bacteria and viruses is commonly described by the term "air disinfection."

During the past five years the Office of the Surgeon General of the Army, the Bureau of Medicine and Surgery of the Navy, and the National Institute of Health of the Public Health Service have been actively engaged in studies on "air disinfection." Three methods for reducing air-borne infection in sleeping quarters, barracks and hospital wards have been investigated:

1. Suppression of "dust," particularly through application of oil emulsions to floors, blankets, and bed linen
2. Inactivation of bacteria and viruses in air by ultra-violet radiation
3. Inactivation of bacteria and viruses by germicidal mists or vapors

Before discussing the effectiveness and limitations of these control measures, it will be useful to recapitulate briefly the rationale of air infection and disinfection. Bacteria and viruses of human origin occur in the air in droplets, in droplet nuclei, and in dusts. Droplets originate from secretions of the nose, throat, and mouth. When they are expelled during talking, coughing, spitting, and sneezing, the larger droplets quickly settle out of the air and desiccate on nearby surfaces, including floors, table tops, clothing, and bedding. The smaller droplets lose their moisture by evaporation, and the dried residues, called droplet nuclei, float in the air and drift about with its currents. Dust in the air or on surfaces may receive contamination from droplets and droplet nuclei, or from infected materials such as handkerchiefs, clothing, bedding, bandages of infected wounds, and dressings.

The time of survival of microorganisms outside the human body varies for each pathogenic species, according to environmental conditions, from a few seconds to minutes, hours, days, weeks, and even months. Exact knowledge of the relative importance of the limiting factors, which include temperature, humidity, dust concentration, and light, is meager. The bacteria and virus content of the air in enclosed spaces is constantly being replenished from its occupants and from dust that is stirred up by activities of the occupants and by air currents.

While the objective of air disinfection

* Report of the Committee on Sanitary Engineering, National Research Council, Division of Medical Sciences, Washington, D. C.

is reduction, removal, or inactivation of pathogenic organisms, the effectiveness of control devices can only be measured indirectly because of technical limitations. Two methods of measurement are available:

1. Sampling the air for all microorganisms that will grow under the conditions of culture, or for specific organisms such as hemolytic streptococci, Group A.

2. Observing and recording the incidence of specific clinical or subclinical infections or cross-infections, occurring in a group of persons or animals living in quarters in which disinfection is in use, and comparing this incidence with that of a control group living in similar untreated quarters. The comparative index may be (1) an infection rate, as determined by bacteriological culturing of nose and throat swabs taken at frequent intervals; (2) a sickness rate including all forms of minor respiratory illness; or (3) a sickness rate based upon hospital admissions for specific respiratory illness.

The second group of methods are both elaborate and time consuming. They require a pooling of skills of engineers, physicists, bacteriologists, clinicians, and epidemiologists. Progress is very slow, as the following review will indicate, and generalizations and inferences must be drawn with great care.

DUST LAYING MEASURES.

Dust and lint control is discussed first solely for convenience in presenting the material with a minimum of repetition. Experiments^{1, 2, 3} have shown that dust and lint particles, which are normally dispersed by air currents, sweeping, bed making, or walking, greatly reduce the effectiveness of ultra-violet irradiation or the use of aerosols by protecting airborne organisms from the action of these agents.

Practical means for meeting this challenge were first studied by van den Ende and Andrews,^{2, 4} and later by the U. S. Navy and Army. In the experience of Naval Medical Research Unit No. 1,⁵ droplet-dust particles appeared to constitute the chief source of intra-ward

infections under conditions of war hospitalization. Oiling of floors proved effective and economical in controlling droplet-dust particles for periods of at least two weeks. Scrubbing floors with water or glycols was inferior to oiling and did not offer lasting protection of adequate value. It has been recommended, therefore, that floor oiling be used where practical as a routine sanitary measure, particularly in barracks mess halls, or temporary hospital quarters during short epidemic periods.

The Commission on Air-borne Infections, Army Epidemiological Board, Preventive Medicine Service Office of Surgeon General, U. S. Army, has investigated the effect of oiling floors and bedclothes on the bacterial population of air and on the incidence of acute respiratory diseases in troops. In preliminary experiments at Camp Carson,⁶ oiling of floors in barracks with pale paraffin oil reduced the peak of bacterial dispersion by 70 per cent during hours of maximum activity, and treatment of blankets, mattress covers, sheets and pillow cases with an emulsion of medicinal mineral oil, in addition to oiling floors, effected a reduction of 80 per cent in total bacterial counts. Comparable results were obtained in the station hospital wards following application of these measures.

Hospital admissions for respiratory infections at Camp Carson were fewer in a group of 5,750 men living in barracks with oiled floors than there were in a comparable group living in untreated barracks. Oiling bedding as well as floors appeared to be still more promising.

A more extensive study was carried out jointly by the Commission on Air-borne Infections and the Commission on Acute Respiratory Diseases at the Field Artillery Replacement Training Center, Fort Bragg, during the winter of 1944-1945.⁷ The floors and bedclothes in alternate barracks of four battalions

were treated with oil,^{8,9} and the intermediate barracks were used as controls. These measures lowered the bacterial count by 75–90 per cent and resulted in almost complete elimination of dust. Although hospital admissions from the oiled barracks were fewer in November and December (1944) when the incidence of respiratory disease was low, there was no significant difference in January and in succeeding months when the incidence was high. Acute undifferentiated respiratory disease (ARD) predominated while the prevalence of hemolytic streptococcus carriers remained low throughout the period of study.

It was concluded that "dust suppressive measures were of little practical value in controlling respiratory diseases among new recruits under conditions which were present and for the diseases which occurred during the winter of 1944–1945 at Fort Bragg." Close contact or droplet nuclei seemed to be more important than contaminated dust in the spread of ARD.

Wright, Kruickshank, and Gunn¹⁰ were unable to control the spread of dust-borne hemolytic streptococci in measles wards by oiling floors alone, but they obtained some measure of success by the additional oiling of all bed-clothes, ward-linen, and patients' garments.

More favorable experience has been reported from a British Military unit housing 1,300–1,700 men.¹¹ Treatment of wooden floors with spindle oil at regular intervals was associated with an incidence of common respiratory diseases of 7 per 1,000 as compared with one of 38 per 1,000 in an untreated control unit.

Good results were also obtained by Feasby and Bynoe¹² of the Canadian Army, working with hemolytic streptococcus infections. A substantially lower carrier rate was observed in barracks in which oiled sweeping compounds were

used as contrasted with barracks that were swept in the usual manner. As a result of this and other studies, a routine order was passed on July 12, 1944, making the oiling of floors mandatory in all Canadian Army buildings.

ULTRA-VIOLET IRRADIATION

The bactericidal property of ultra-violet radiation has long been known. Wells and Fair¹³ were the first to apply this principle to the disinfection of air in 1933. Since then many important contributions to the literature have been made, notably by Wells, Hart, Wilson, Hollaender, Andrews, Doyle, and others,² using upper air irradiation or ultra-violet curtains. Hollaender and his coworkers¹⁴ have recommended the irradiation of air under bunks, and floor dust as well as the upper air.

The physical aspects of ultra-violet disinfection have been discussed by Wells,¹⁵ Buttolph,¹⁶ Rentschler,¹⁷ and others.

UPPER AIR AND FLOOR IRRADIATION IN BARRACKS

An extensive study of the efficacy of upper air and floor irradiation in reducing respiratory infections in barracks was carried out at Camp Sampson, New York, during 1943–1945, by the Bureau of Medicine and Surgery, Navy Department with the coöperation of the National Institute of Health.¹⁸

A self-contained unit comprising 22 two-story barracks was divided into four groups of approximately 1,250 men each. One group was subjected to radiation of high intensity, 235 watts of ultra-violet energy per dormitory of 112 men; and a second to low intensity, 121 watts per dormitory. Third and fourth groups served as controls. Alternate barracks were irradiated and the adjacent untreated barracks were used as controls. In addition to overhead lights, an ultra-violet lamp was installed

under alternate bunks to irradiate the lower air and floor dusts. With a training period of 4 to 6 weeks, 15,000 men were observed in the two test groups and 15,000 in the control group between December 15, 1943, and June 1, 1944.

During this period, hospital admissions for respiratory infections were 25 per cent lower in the group of men exposed to high radiation intensity than in the control group. During the first $2\frac{1}{2}$ months of the study, when illness rates were high, the difference in admissions averaged 35 per cent. On the other hand, there was no significant difference in hospital admissions from the low intensity group and its control.

Negative results with low ultra-violet intensities have been reported also by Schneiter, *et al.*¹⁹ at the National Training School for Boys, in Washington, D. C., and by Lurie²⁰ working on the spread of the tubercle bacillus in rabbit colonies through the medium of air.

Bacterial counts in irradiated and control barracks at Camp Sampson showed up to 50 per cent reduction in counts of total bacteria and a significant lowering of beta-hemolytic streptococci isolated from air and dust.

This study was continued during the winter of 1944-1945 with high ultra-violet intensity in all test barracks and with additional floor lamps to irradiate central aisles. The training period was increased to 10 weeks, while the total number of men remained unchanged. The average reduction in hospital admissions during 1944-1945 was about 18 per cent.²¹ No definite conclusions were drawn because in January, 1945, sulfadiazine was administered to both irradiated and control groups for 3 weeks as a prophylactic measure against a threatening epidemic of scarlet fever.

ULTRA-VIOLET IRRADIATION SUPPLEMENTED WITH DUST CONTROL MEASURES

These experiments²² too were carried

out at Camp Sampson using 22 barracks of Unit D which housed a maximum of 5,280 men. Floors, blankets, mattress covers, and pillow slips in 15 barracks were treated with emulsified mineral oil developed by Naval Research Unit No. 1.⁵ Seven of the "oiled" barracks were equipped with high-intensity irradiation, using ceiling, underbunk, and center-aisle lamps. The remaining 7 barracks served as untreated controls. Each control barrack was sandwiched between an oiled barrack and one which was treated with both oil and ultra-violet light.

Bacterial counts were 75 per cent lower in oiled than in unoiled barracks. Alpha and Beta hemolytic streptococci were greatly reduced in number by oiling, and were practically eliminated from the air by combined action of oiling and irradiation. Most of the organisms were concentrated near the floor and decreased in numbers toward the ceiling.

In comparison with untreated control barracks, hospital admissions for upper respiratory infections during 1944-1945 from barracks in which ultra-violet irradiation was supplemented with oiling of floors and bedclothes were reduced in the same order of magnitude as during 1943-1944. The oiled barracks without irradiation showed a reduction of about 10 per cent. This has not yet been established as a statistically significant difference. The investigators point out that these are preliminary data, not yet acceptable, because the study period was only 3 months; also confusion in the issue of oiled blankets obscured the findings. However, a combination of irradiation with oiling appeared to be promising. The study is being continued at the Great Lakes Naval Training Station.

PRECAUTIONS IN THE USE OF ULTRA-VIOLET LIGHT

Direct irradiation of sufficient in-

tensity to kill microorganisms in air is also harmful to the eyes and exposed skin of human beings, particularly to conjunctivae which lack the protection offered by horny cells. Exposure for less than a minute may produce painful conjunctivitis after a latent period of several hours. However, no permanent eye injury has yet been reported in the literature of air disinfection. Much like sunburn, direct radiation on the skin may cause severe erythema and blisters after a latent period of a few hours.

It is therefore necessary to irradiate the ceiling and upper air well above head levels. In particular, must lamps be equipped with baffles that will confine the powerful rays to a region well above or below the normal line of vision. Control of air quality in the breathing zone is then effected by natural or forced circulation which displaces or dilutes contaminated air with irradiated upper air or lower layers. It should be kept in mind that some walls, ceilings, and floors will reflect injurious radiations. Ultra-violet light meters are now available for measuring intensities down to the limits of human tolerance.

The Council of Physical Therapy of the American Medical Association has tentatively recommended that the total ultra-violet intensity of wave length 2537A (including reflection from ceilings, walls, and fixtures in addition to direct emanation from lamps) falling on occupants be not more than 0.5 microwatt per sq. cm. for exposures of 7 hours or less, and not more than 0.1 microwatt per sq. cm. for exposures of 24 hours a day.^{23, 24} Responsibility for protecting occupants in irradiated spaces falls largely on lamp manufacturers and installers, who should measure the energy distribution and output efficiency of their fixtures as installed. Periodic testing of energy output and cleaning of fixtures is essential if functional efficiency of installation is to be maintained.

Ultra-violet lamps used for air disinfection may produce ozone in objectionable concentrations, particularly when they are new. If the odor becomes distinctly perceptible the Council recommends increased ventilation.

AEROSOLS AND GLYCOL VAPORS

During the influenza pandemic of 1918, Masterman²⁵ found that spraying the air with dilute solutions of hypochlorites reduced the number of infected particles in the air and apparently lowered the incidence of influenza in crowded cotton mills. Various other chemical aerosols or mists have been tried since 1918 with limited practical success owing to their toxicity, odor, unpleasantness, or destructiveness to fabrics and metals.

LABORATORY STUDIES OF GLYCOL VAPORS

The use of pure glycols for disinfecting air was first disclosed by Robertson and his associates²⁶ working at the Medical School of the University of Chicago under the auspices of the Surgeon General, U. S. Army.

Laboratory experiments^{27, 28} in a glass chamber of about 2 cu. ft. capacity, and in a room of 800 cu. ft., showed that concentrations of 1 gm. of propylene glycol vapor in 2,000–4,000 liters of air, or 1 gm. of triethylene glycol vapor in 100,000–200,000 liters of air produced almost immediate and complete sterilization of air into which streptococci, pneumococci, influenza virus, and other organisms had been sprayed. Tests with mouse-adapted influenza virus A on Swiss mice revealed that the glycol vapor protected mice completely against an amount of air-borne virus that killed all control animals.

BACTERIOLOGICAL TESTS WITH GLYCOL VAPORS IN ARMY HOSPITALS

Hamburger, Puck, and Robertson²⁹ carried out preliminary field tests at the Army Hospital at Chanute Field, Ill.

Triethylene glycol vapor in concentrations near the saturation point (0.01 mg. per. lit., moderate fog) reduced the number of air-borne beta-hemolytic streptococci by about 75 per cent in a ward housing patients convalescing from scarlet fever. By injecting steam into the air from the heating system, the relative humidity was kept between 30 and 60 per cent during test and control periods.

In two German measles wards, triethylene glycol vapor lowered the number of air-borne hemolytic streptococci by 60 per cent. Streptococcal cross-infection is reported to have ceased following glycolization, but there were no control data to make sure of this finding.

Failure of glycol to produce rapid and complete sterilization of air in these wards, is ascribed to protective action of dried dusts and lint on which bacteria abound.

A combination of triethylene glycol vapor and dust control was tried out by the same authors³⁰ in hospital wards at Camp Carson, Colo. Floors were treated daily with a solution of 5 per cent urea, 3 per cent ninol, and 0.1 per cent roccal to hold down dust. Mattress covers, sheets, pillow cases, blankets, pajamas and bathrobes of patients were treated with 2 per cent oil emulsion. Glycol concentration was maintained close to the saturation point with temperatures between 71 and 77° F. and relative humidities of 40-45 per cent.

The combination of triethylene glycol vapor and oiling effected a reduction of 93 per cent in the number of air-borne hemolytic streptococci when the wards were quiet, and 97 per cent during bed-making periods.

Oiling of floors and bedclothes alone, without glycolization of air, reduced the streptococcal count by 86 per cent during bed-making but not at all during quiet periods.

EFFECT OF GLYCOL VAPOR ON THE INCIDENCE OF AIR-BORNE INFECTIONS

Preliminary experiments by Harris and Stokes³¹ working at the Children's Seashore House in Atlantic City, N. J., under the auspices of the Surgeon General's Office of the Army, have indicated a marked reduction of upper respiratory infection and of total bacterial count during periods of glycolization. The number of patients studied, however, was relatively small; most of the children were bedfast in a supine position; and there was a minimum of direct contact or droplet spread in the wards.

Bigg, Jennings, Olsen³² tried out triethylene glycol vapor in two similar barracks, each housing 320 men in four dormitories. With a training period of 6 weeks, three groups of 320 men each came under observation in four test dormitories in which the triethylene glycol concentration was maintained between 0.0025 and 0.004 mg. per lit. An equal number of men served as controls in four untreated dormitories. Hospital admissions for "air-borne diseases" during the first and second training periods averaged about 12 per cent lower in the test than in the control group, and there was a marked reduction in the incidence of hemolytic streptococci in throat cultures. Data obtained during the third period were inconclusive, presumably owing to variables introduced by warm weather.

Less favorable results were obtained by the Commission on Air-borne Infections at the Lockheed Aircraft Plant³³ where triethylene glycol vapor was tried out as a prophylactic measure against "colds." Although the male employees of the test group reported fewer colds than did those in the control group, no significant difference in colds was found in females of the two groups. The colds reported by both men and women of the experimental group were

more severe than those reported in the control group. This is ascribed to individual differences of criteria used by examining nurses.

Essentially negative results were reported by Mather and McClure³⁴ working with propylene glycol in Canadian Air Force Barracks. Concentrations of less than 0.1 mg. per lit. showed little bactericidal action and had no effect on respiratory illness or on hemolytic streptococcus carrier rate. Concentrations greater than 0.1 mg. per lit. proved definitely bactericidal but were impracticable to maintain owing to excessive condensation on windows, walls, doors, despite the unusually mild weather prevailing during the period of the study.

IMPORTANT FACTORS IN GLYCOL VAPOR DISINFECTION

Glycols are not chemical disinfectants in the ordinary sense. Their action in air apparently depends on hygroscopic properties and their potency is at a maximum in saturated concentrations. The degree of saturation, rather than absolute concentration is the important factor. According to Robertson,³⁵ the ideal glycol concentration for air sterilization is one just below the saturation point with low rather than high temperatures and with relative humidities between 40 and 60 per cent. Glycol saturation increases progressively with rising temperature and humidity. Since it is difficult accurately to control bactericidal glycol levels, particularly of triethylene glycol, a moderate fog must be maintained at all times which is likely to cause excessive condensation and produce undesirable psychologic effects.

With propylene glycol, a concentration of 0.3 mg. per lit. (67 per cent saturation) was found decidedly oppressive and the air felt humid and possessed a stale sweetish odor. Considerable condensation of glycol solution occurred

on windows. Paints became sticky after several hours of exposure to this concentration. However, no toxic effects were observed in persons breathing the vapor for a period of 4 hours.³⁶

Mather and McClure³⁴ record similar experiences. With propylene glycol concentrations of 0.2 mg. per lit. or less, heavy condensation occurred and the men complained that the barracks were too warm and stuffy and had a bad odor. Some reported that their throats were sore and dry on awakening in the morning. Overheating of barracks due to unusually mild weather is believed to have been responsible for some of these complaints.

Triethylene glycol has a lower vapor pressure than propylene glycol, and its saturation concentration and possible toxic effects are, therefore, less. In laboratory studies by Robertson,³⁵ atmosphere saturated with pure triethylene glycol vapor produced no toxic effects on rats and monkeys exposed continuously for about one year. In field studies by Hamburger, Puck, and Robertson,²⁹ carried out during cold weather, patients readily adapted themselves to saturated concentrations with no harmful or irritating effects during the limited period of study.

When the temperature of the glycolized air is high, complaints may be high even after short exposures, because the glycol concentration required to approach saturation increases sharply with temperature. The indications are that glycolization in warm weather is undesirable and impractical unless the temperature is reduced by refrigeration.

Another practical drawback to the use of the triethylene glycol is its low volatility and the small range between bactericidal and fogging concentrations. These introduce difficulties in securing even distribution and control of glycol concentrations in all parts of a room without inducing condensation. The use of room fans facilitates distribution

but may cause uncomfortable drafts. Opening windows and doors seriously aggravates the distribution problem.' An automatic controlling device described by Puck, Wise, and Robertson³⁷ helps but does not entirely solve the problem.

Owing to excessive condensation of the vapor inside the ducts, distribution of glycol vapor through conventional duct ventilating or 'air conditioning systems' is also troublesome, particularly in warm weather.

In vaporizing glycol for air disinfection, it is important to keep in mind that glycols disintegrate at boiling temperatures under normal atmospheric pressure to produce acrolein which is extremely irritating to the throat and lungs. The disintegration temperature of triethylene glycol is placed at 260° F.³⁸

DISCUSSION AND RECOMMENDATIONS

It appears from the foregoing review that a first step in the disinfection of air in barracks, wards, and similar places of assembly in military establishments is suppression and removal of dust and lint particles. The oiling of floors and blankets and, in hospital wards, of sheets and pillow cases, has been shown to be a practical, cheap, and effective measure. It reduces the bacterial content of the air, and there is evidence that it may in some degree reduce the risk of transmission of certain bacterial infections, particularly those due to hemolytic streptococci, Group A. A reduction in the risk from virus infections has not been demonstrated, although some experimental work with influenza virus suggests this possibility. On the basis of present studies, both the Army and the Navy have accepted the oiling or related treatment of floors for dust control and the oiling of bed clothing under appropriate circumstances as recommended sanitary practice.

Experimentally it has been established that, under ideal laboratory con-

ditions, bacteria and viruses suspended in the air as finely dispersed particles can be rapidly inactivated by exposure to adequate concentrations of triethylene glycol vapor. In the glycolization of the air of barracks, hospital wards, and similar places of assembly, under actual conditions of use and occupancy, however, there were a number of factors that limited its effectiveness. It has been shown that under the most favorable circumstances, triethylene glycol vapor will reduce the total number of bacteria (or the number of bacteria of a pathogenic species, such as the hemolytic streptococci, Group A) in the air by as much as 90 per cent. However, this is not a measure of effectiveness in reducing the spread of respiratory infections. Under natural conditions dispersed aggregates of bacteria and viruses carried by air currents represent only one of the channels by which infection travels from person to person. Others exist, too. Infective particles may pass directly from one individual to another in face-to-face contact. The heavier infective particles, including lint from contaminated blankets, bedding, clothing, and handkerchiefs, may accumulate in dust in the immediate environment of an infected individual and will then constitute an important channel for short range transmission of infection. The possibility of indirect transmission of infection by the handling of contaminated objects cannot be ignored. Undoubtedly the relative importance of these channels varies with the ability of different pathogenic agents to survive in the external environment and with the conditions of occupancy, the extent of crowding, and the kind of activity carried on. Examples are, hospital wards in which patients are confined to their beds or in which patients are ambulatory, classrooms, moving-picture theaters, dispensaries, and drill halls.

Up to the present, studies of the value of ultra-violet light and of triethylene glycol vapor in reducing the incidence of respiratory infections have been largely confined to barracks and hospital wards. The data available suggest that under some circumstances these both may have a measurable effect upon the attack rate from certain respiratory diseases, but experience is not sufficient to justify drawing definite conclusions.

The two primary conditions for the successful application of ultra-violet light to the disinfection of air are: (a) supplementing irradiation with dust suppression measures, since ultra-violet light is not efficient against bacteria and virus protected by dust; and (b) attaining a radiation of sufficient intensity but not so high as to affect the eyes or skin of occupants.

The use of triethylene glycol, too, must be supplemented with dust control measures if it is to be successful. The glycol concentration should be just below the saturation level with low rather than high temperatures. The glycol must be pure, made especially for air disinfection, and the vaporizing device must operate at relatively low temperatures. Glycolization of air at high temperatures is undesirable and impractical.

Admittedly, both ultra-violet light and glycols have their merits and demerits. Present knowledge is too limited to make any definite claims or predictions concerning their ability to reduce air-borne infection. The design and operation of apparatus for air disinfection is still on an empirical basis and the use of these disinfecting agents is not without danger (to the user). Extravagant claims for promotion of sales of disinfecting apparatus at this time may well retard progress and injure the industry.

The committee does not recommend the general use of these disinfecting devices for the present. Much research

and development work by qualified personnel remains to be done.

Criteria for the Allocation of Subsidy to Local Health Departments*

JOHN A. KAHL, M.D., M.P.H.

*Assistant State Director of Health in charge of Local Health Services,
State Department of Health, Seattle, Wash.*

THE subject that I am to discuss today is perhaps one that is more controversial than any problem in the field of public health. One can bring together almost any group of state public health administrators and attempt to discuss a plan for the allocation of state and federal funds to local health departments, and have as many opinions of how it should be done as there are participants.

Recognizing this situation, I certainly do not propose that I can bring a final answer to health officers, but I shall attempt to outline some of the fundamental considerations which we believe in the State of Washington do assist us in doing a better job of administration for our local health departments.

First, I would like to say that we will never develop a single satisfactory, detailed plan that can be applied to every state in this nation. Furthermore, I would like to emphasize that no plan can be followed to the letter in each and every community in a state. But there are certain basic principles which make a plan of valuable assistance.

The desirability of a plan is known to all of you.

1. It provides the state administrator with a basis for an orderly and equal division of state and federal funds to local health departments,

thus avoiding dependence on opinion and impression.

2. It gives assurance to the state legislators and to the state administration that the funds available are being distributed to the communities of the state on a fair basis.

3. It provides the local health administrator with some assurance and understanding of what financial assistance he can expect from the state.

4. A plan, properly developed, will stimulate local health administrators and other local officials to increase local contributions if they know financial assistance will be forthcoming from the state.

5. If the plan is applied only to full-time health departments, as it should be, it will stimulate their development, and will further assist in developing them in accordance with the state overall plan for complete coverage by full-time health services.

Assuming that we have suitable legislation for the development of local county, city, and district health departments on a full-time basis, then the plan should embody certain principles:

1. It must recognize that all units of local government do not have the same financial ability to provide the necessary government services, including public health. Therefore there must be a method of equalizing these financial differences so that all counties can provide at least minimum health services.

2. It must stimulate local financial participation.

3. It must provide for financial participation by the state in each local health unit if a basis for state guidance is to be successfully developed.

4. It must take into consideration the various special problems and needs of the various individual communities.

* Presented before the Health Officers Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 13, 1946.

within their financial ability we have developed the next step of the plan.

First we set aside a small amount of money for special needs, which will be discussed later. This in the past has amounted to approximately \$60,000 per year. With the remaining amount of state money we determine through trial, using as the basis the assessed valuation for each county or district, the maximum per capita amount in which we can participate on a matching basis. This at present is \$.75.

We have devised a guide for matching on the basis of assessed valuation per capita, since this is the only method upon which the county can raise additional revenue in our state. The guide is as follows:

1. The county with an assessed valuation up to and including \$500 per capita earns \$2 of state money for each \$1 of local money raised above the mandatory levy;
2. For each county with an assessed valuation from \$500 to \$1,000 per capita it earns \$1 of state money for each \$1 of local money raised above the mandatory levy;
3. For each county with an assessed valuation of \$1,000 or over per capita it earns \$1 of state money for each \$2 of local money raised above the mandatory levy.

We arrived at this plan by determining the assessed valuation per capita for all of our 39 counties and then grouping them into thirds. We found that the average per capita assessed valuation was \$880 and that the lower third was \$500 or less, and the upper third was \$1,000 or more.

We have determined as previously stated that we can match up to \$.75 per capita with the money available at present. However, we place two limitations upon granting the full amount earned.

1. If the county or district does not raise sufficient local money to match state money to reach the \$.75 per capita, we only grant the amount that they can match. But we may if indicated give a temporary grant for special needs.
2. We reserve the right not to grant the

entire amount earned if we know the county cannot or will not wisely utilize this money.

Reference to column 4 will show the amount of money per capita needed to bring the unit to \$.75 per individual. In column 5 is given the ratio of matching determined by using the assessed valuation per capita found in column 13, and applying it to the matching guide described.

In column 6 is given the amount of local money needed for matching and the amount of state money needed for matching will be found in column 7. Column 8 shows the amount of state money actually granted.

If the county's minimum mandatory levy exceeds \$.75 per capita, we do not grant any funds on a matching basis. However, as additional money does become available, we hope to match to \$1 per capita, or more.

In column 11 you will see that this procedure has been instrumental in increasing local funds far in excess of the minimum mandatory levy.

In order to make the plan flexible, we provide grants for special needs mentioned previously, and in our state these are:

1. Counties with a rapid increase in population resulting from war or industrial developments.
2. Counties containing large areas of federal land. As you know, these lands are tax-free, yet the county has the responsibility for providing health and police protection, as well as roads. We, therefore, attempt to compensate these counties for loss of revenue.
3. In the development of new health departments in order to demonstrate the value of good full-time health services, and thereby gain more active local support, including financial participation.
4. Demonstration purposes, principally to develop new and expand old programs and sell them to the local community.

In column 9 are presented the grants for special needs to the counties and districts. We like to think of special grants in most instances as temporary

assistance; however, in a few areas they will be continuous.

It will be noted that we are putting some state money into each full-time county or district health department; in some instances it is very small, but we feel it is sound administration (see column 10).

In summary I shall outline a few principles for the allocation of state subsidy to local health departments. Such principles, I feel reasonably sure, can be applied in any state. These should include:

1. A minimum mandatory financial requirement for each unit in the development and maintenance of its full-time public health department. This can either be a requirement by the state department of health before it will participate financially, or it can be, as in our state, a legal requirement.

2. There should be an equalizing factor because of financial variations and ability of counties to pay for public health service. This assistance may be based upon per capita income, expendable wealth per capita, or assessed valuation per capita. It will depend principally upon which method is the most practical for each individual state.

3. The plan should be so devised as to stimulate local government to increase financial support to a desirable maximum in the development and maintenance of its full-time health services.

4. The plan must be sufficiently well defined and publicized so that local health administrators and local officials will know what they can expect from the state in the way of financial assistance, on a long range basis.

5. The state should participate financially in every full-time health department in order to be in a position to exert some degree of guidance in the development of sound public health programs.

6. The plan should encourage the development of new and the expansion of old programs through some method such as special grants or grants for demonstration purposes.

Finally I would like to point out that this formula has been in operation in the state of Washington since 1940, and during this period it has had some rather rough going because of situations during the war period. It is, however, well accepted by the health officers in

the state and certainly it has been invaluable to me as the Director of Local Health Services during most of this period.

ANALYSIS OF EACH COUNTY AND DISTRICT

1. *Benton-Franklin Health District*—Special grant of \$4,376.00 was given because of rapid growth of population. In this area is located the atom's bomb plant at Richland.

4. *Cowlitz-Wahkiakum Health District* — Column 14 shows a special grant of \$8,014. Much of this was given on the basis of developing a satisfactory tuberculosis survey program. However, a small amount of this was given to assist the health department in giving increased services to the two major cities, one of 7,000 and the other of 12,000 in order to get them to participate.

5. *King County Health Department*—A special grant of \$5,680 was given on the basis of putting some state funds in each local department.

6. *Kitsap County-City Health Department* —The population of this county before the war was about 35,000 and did reach a figure of about 125,000. The population is rapidly decreasing and until some local census survey is made we will be unable to determine accurately what the population is; however, it is generally guessed that perhaps it is in the neighborhood of 70,000 at present, although we show 108,000. This accounts for the minus figure of \$18,315. This population will probably recede to about 50,000. In addition during the war the American Red Cross supplied approximately \$10,000 per year to this district for nursing service.

7. *Kittitas County Health Department*—In column 14 there is a grant of \$1,574. Approximately one-third of this county is national forest land. We will undoubtedly need to continue and increase the special grant to this county. However, it is hoped that at some future date we may combine it with Yakima County.

8. *Lewis-Pacific Health District*—This area has been without a full-time health officer for the last 2½ years. For that reason they are not in a position to use their full grant. However, they want a full-time health officer as soon as they can obtain one, and we will increase our grant.

9. *Mason-Thurston Health District* — A special grant of \$1,278 has been given because Mason County is about one-third national forest land.

10. *Clallam-Jefferson Health District*—This area has a special grant of \$6,177 on the

basis that approximately half of this area in each county is in the Olympic National Park.

11. *Okanogan County Health Department*—A very large county composed of three valleys, requiring long trips. Two-thirds of this county is national forest service land. Therefore, a grant of \$1,770 was given. The county is so large that it cannot be successfully combined with another county; although the population is small we will probably have to increase special aid to this county.

12. *Pierce County Health Department*—A special grant of \$7,593, principally for the development of a satisfactory maternal and child health demonstration.

13. *Snohomish County Health Department*—A special grant of \$6,070 to provide some services and demonstrate effectiveness of public health to the first class city, Everett, with a population of about 35,000, which is now a part-time unit, in order to get a combined unit eventually.

14. *Spokane County Health Department*—The grant was \$2,040 on the basis of putting some state money in each local unit.

15. *Walla Walla County-City Health Department*—A grant of \$7,948 on the basis of a large Veterans' Hospital for tuberculosis, an Army General Hospital of some 5,000 beds, which is now closed, and a large bomber training base. This grant will decrease.

16. *Yakima County-City Health Department*—The first class city in this district contributes large financial support and the health department has not sufficiently developed to a place where it can wisely utilize the additional money, so we have not granted them approximately \$26,000 they earn. Eventually they will obtain this money when they can wisely utilize it.

17 and 18. *Whatcom County-City Health District* and *Grays Harbor County* are both new districts and have not developed to a point where they can utilize additional money. This is due to personnel shortages.

1946 a Record Health Year in New York City

On New Year's Day, 1947, Health Commissioner Israel Weinstein, M.D., released a summary report of the work of the New York City Department of Health in 1946. He found many evidences of a healthy community. More babies were born than in any previous year in the city's history and the birth rate was higher than in any year since 1927. Both the infant and maternal mortality rates were the lowest on record. The general death rate was 10.1 per 1,000 population, a record bettered only in 1941 when the rate was 9.9 and in 1938 and 1942 when it was 10.1. The tuberculosis, pneumonia, and appendicitis death rates were the lowest on record; accidental deaths were lower only in 1944. There was an increase in reported cases of infectious venereal diseases.

Among the communicable diseases of childhood, whooping cough and scarlet fever deaths each decreased, the latter

almost to the vanishing point. The 18 diphtheria deaths were the largest number since 1939. The measles death rate was equal to that of 1943 and 1944 but higher than 1945.

Diabetes deaths decreased slightly both in number and rate; cancer deaths and the death rate were practically stationary. Approximately half of the nearly 78,500 deaths were of persons over 60 years of age.

Among the special events of the year were the outbreak and discovery of "Rickettsialpox" spread by mice, a continued increase in the number of chest x-rays, more than 12 times the number of persons x-rayed in 1944, an intensive city-wide program of restaurant sanitation, a ragweed destruction program through which 3,000 acres of growing ragweed were destroyed, and the completion of the micro-filming of all birth, death, and stillbirth certificates for the years 1847 to 1945.

A Darkfield Colony Illuminator

RONALD M. WOOD

Department of Bacteriology, School of Medicine, Johns Hopkins University, Baltimore, Md.

THE illuminator herein described gives a transverse light across the Petri dish and illuminates the individual colonies by the darkfield principle.

Light is conducted to the rim of the Petri dish by an acrylic resin or similar material having the same optical properties (e.g., plexiglass, lucite, polystyrene, etc.): In this model the plastic is $9/64$ – $5/32$ inch in thickness and has a circular opening $3\frac{3}{4}$ inches in diameter to accommodate the lower section of the Petri dish. The edges (b, Figure 1) are bent to pick up the light from an ordinary light bulb. The plastic is covered with a piece of metal (a) (one side being cut away for purpose of illustration) having an opening of the same size. A piece of metal (c), painted black, serves as a support on which the Petri dish rests. The as-

FIGURE 1—Darkfield colony illuminator

FIGURE 2—Colonies as seen over a Brown counting chart in the illuminator

sembly is arranged in conjunction with the light source so that it can be adjusted to any convenient angle. In use, the Petri dish is placed in the opening (d). All sizes of colonies stand out brightly against the black background. With this illuminator pinpoint colonies are easily distinguished from small particles in the medium. A magnifying lens may be used if desired. The model illustrated in Figure 1 is in actual use but is capable of further mechanical refinement.

This illuminator* can be used with colony counting charts such as described by J. Howard Brown (Figure 2) on page 206. It is of simpler and less expensive construction than other illuminators on the market.

* Available from Baltimore Biological Laboratory, Inc.

Charts for Counting Bacterial Colonies

J. HOWARD BROWN, PH.D.

Department of Bacteriology, School of Medicine, The Johns Hopkins University, Baltimore, Md.

THE charts illustrated are of the diameter of the bottom of a Petri dish and are used for counting bacterial colonies in agar plates. The colonies may be counted by daylight, by the light of a desk lamp, or by means of an illuminator such as described by Ronald M. Wood.¹ The last gives the best illumination. If daylight or a desk lamp is to be used, a chart is placed into the lid of a Petri dish and the agar plate to be counted is placed, bottom down and without lid, into the lid containing the chart. It may be held securely in place by a rubber wedge. With the light falling on to the plate obliquely from above, the colonies appear white against the black background. A suitable magnifying glass may be useful.

Four charts are illustrated. The $\times 1$ chart is to be used when all colonies in the plate are to be counted. Chart $\times 2$ is to be used when $\frac{1}{2}$ of the colonies are to be counted, chart $\times 5$ when $\frac{1}{5}$, and chart $\times 10$ when $\frac{1}{10}$ are to be counted. Charts $\times 2$, $\times 5$, and $\times 10$ are ruled radially so that the areas in two pairs of opposite sectors represent $\frac{1}{2}$, $\frac{1}{5}$ and $\frac{1}{10}$, respectively, of the area of the plate. All of the colonies in the four sectors should be counted and the result multiplied by the indicated factor. The counting of four sectors at right angles to each other helps to compensate for uneven distribution of colonies in the plate. Since the length of every arc of a sector is in similar ratio to the circumference at that point, all areas from the center to the periphery of the plate are given

proportionate evaluation, which is not true when a guide plate ruled in squares is used and consecutive squares are counted vertically and horizontally. Variations in the diameters of dishes do not enter into consideration.² It is obvious that these advantages do not exist in counting plates ruled in squares; hence the radial ruling results in greater accuracy and simplicity of calculation. Radial ruling was also employed in the Jeffers³ plate but the subdivisions on this plate make calculation rather complicated. The subdivisions within the sectors of the charts here described and within the lines on the $\times 1$ chart are purposely no calculated part of the sector or plate, the lines serving merely as guides to the eye. It is, therefore, impossible to slight the work of counting the colonies in an entire sector or the entire plate as the case may be. The practice should be to employ such a chart that no fewer than 100 colonies will be found in the four sectors to be counted. If there are fewer than 100 colonies in the plate all should be counted.

Similarly ruled charts have been tried for counting colonies against a white background illuminated by transmitted light, but we have obtained better results by counting against the dark background with reflected or darkfield illumination and there is less eye strain. The charts* are inexpensive and may be discarded when soiled or worn.

* Available from Baltimore Biological Laboratory, Inc.

THE STORY OF BRUCELLOSIS

WE are fortunate in presenting—as the Special Review Article for this issue—an address read by Dr. Alice C. Evans at the First International Congress for Brucellosis last fall.

Dr. Evans tells us that contagious abortion in cattle is at least a century old in the United States, having been described in New York State as early as 1843. The first human case of undulant fever was reported by Craig in 1906, but believed by him to be a tropical disease caused by contact with a hospital patient. In 1911, Malta fever was described in Texas and the local name of "goat fever" was cited. In 1914, came the first description of contagious abortion in swine.

Dr. Evans and Dr. Eichhorn in a laboratory "bull-session" pooled the viewpoints of bacteriology and pathology and hit on the idea that the three diseases (Malta fever of goats, and contagious abortion of cattle and swine) might be closely related. By 1918, Dr. Evans proved that *Bacillus melitensis* and *Bacillus* (later *Brucella*) *abortus* were indeed identical organisms; or—at most—closely related variants of the same species. In 1924, Keefer described a human case of undulant fever in an employee of a slaughterhouse, the first case of this human disease traced to any animal source other than the goat, which had long been recognized as a host of "Malta fever." By 1927, 217 human cases of what had then come to be known as brucellosis were reported and by 1938 the number had risen to 4,000 cases a year, a figure which has remained fairly constant since that time. This is the disease once called undulant fever in man (a name which should now be abandoned); and caused by any of the three types of *Brucella abortus* causing Malta fever in goats and contagious abortion in cattle and swine.

Whether the importance of this disease was merely unrecognized prior to 1927, or whether the bovine and porcine strains have acquired greater virulence in recent years, no one can say. That the disease is now of considerable public health importance seems clear. Dr. Evans herself suffered a long and tedious attack of chronic brucellosis (caused by a laboratory infection) and she speaks with feeling of its effects and of the anxiety due to extended delay in clinical diagnosis. A number of recent studies show that the actual number of cases of chronic brucellosis is at least ten times the number of reported cases, approximately some 40,000 cases a year in the United States. A much higher estimate (4,000,000!) cases is

given by Huddleson but one cannot take very seriously an extrapolation based on incidence in one particular institution.

The problem, however, is a very real one—both for public health officers and for veterinarians; and Dr. Evans's story of its progressive solution is as dramatic as a "mystery story."

DISEASES OF AN AGING POPULATION

A RECENT issue of the *Statistical Bulletin* of the Metropolitan Life Insurance Company¹ contains figures which are, in some respects surprising, and in all respects encouraging. These computations of mortality among industrial policy holders in 1911 and 1945, respectively, show that in one-third of a century the mortality in this large group from major causes, standardized for color, age, and sex had changed as follows:

Cause of Mortality	Deaths per 100,000		
	1911	1945	Per cent Change
Diseases of Heart, Arteries and Kidneys, combined	330	233	—29
Tuberculosis	242	33	—86
Influenza and Pneumonia	141	22	—84
Accidents	87	56	—36
Cancer	76	82	+ 8

It has been commonly recognized that the crude death rates from diseases of the heart, arteries and kidneys, and from cancer have increased solely on account of the changing age distribution of the population. Many of us have not realized that the same thing is true of deaths due to accidents, which are so much more often fatal for those enfeebled by old age. It appears from these standardized rates that mortality for a really comparable population has decreased by some four-fifths for tuberculosis and pneumonia and by about one-third for diseases of the cardio-arterial-renal complex and for accidents (the latter in spite of the development of motor traffic). Cancer remains practically unchanged, the slight increase recorded being rather less than might be expected from improvements in diagnosis.

Yet, in spite of these heartening figures with respect to adjusted death rates—the brute fact remains that actually, today, one person in 400 dies each year from diseases of the cardio-arterial-renal complex and one person in 1,200 dies each year from cancer. These are the outstanding causes of mortality. These are the major public health problems of the future. Therefore the articles in this issue of the JOURNAL on the diseases of an aging population are timely and important.

FULL-TIME HEALTH SERVICE IN ILLINOIS

WE were able last month to present to readers of this JOURNAL a supplement embodying the full proceedings of the conference on local health units held last fall at Ann Arbor. This conference sounded a bugle call for advance in our basic task of extending the advantages of expert health leadership to the entire

nation. Furthermore, we believe that the proceedings of this conference will prove a valuable textbook on public health practice for many years to come.

It is of interest to note how the movement for full-time health service has gone forward in one state—Illinois. In this state, a survey conducted by the field staff of the American Public Health Association in 1941–1942, resulted in a strong recommendation that an attempt be made to obtain legislation which would permit counties to establish and maintain full-time health departments. The survey staff suggested that a state-wide public health committee consisting of influential citizens throughout the state be appointed for the purpose of developing favorable sentiment for the proposed legislation. In accordance with this recommendation, the Illinois State-wide Public Health Committee came into being in 1942 and now consists of several thousand persons from all parts of the state.

The committee was successful in attaining its first objective in 1943. The resulting statute, known as the Searcy-Clabaugh County Health Department Law, was drawn up after consultation with the American Public Health Association, the Illinois State Medical Society, the Illinois State Dental Society, the Illinois Legislative Council, and other interested groups. This bill, while under consideration in the general assembly, had the support of many state-wide agencies and organizations such as the Illinois State Medical Society, the Illinois State Dental Society, the Illinois League of Women Voters, the Illinois Congress of Parents and Teachers, the Illinois Public Health Association, the Illinois Welfare Association, and others. Due in a large measure to the fact that this bill was supported by widespread public sentiment which had been aroused by the State-wide Public Health Committee, it was passed without a dissenting vote in both houses of the legislature and became a law in July, 1943. At this time there was in existence only one full-time county health department. This was the Cook County Health Department which had been established as a Bureau of the Cook County Department of Welfare in 1940.

After the enactment of this enabling legislation, the State-wide Public Health Committee, with the support of the Illinois Department of Public Health and various voluntary public health agencies, took as its next objective the development of local sentiment for the establishment and maintenance of county health departments. In November, 1944, the proposal to establish county health departments was considered in referenda in two counties. In both of these counties the outcome was favorable. In April, 1945, the proposal was considered by three counties, two of which voted to establish health departments. It was not until 1946, however, that public sentiment had been developed to the point that referenda could be held in a considerable number of counties. In November, 1946, the proposal was considered in 18 counties at the general election. In these counties the outcome was favorable in 17. In 10 of the 21 counties in Illinois which have voted favorably upon the county health department proposal, emergency health departments had existed during World War II. The influence of this experience and of the work done by the State-wide Public Health Committee through the activities of local committees in counties in which campaigns for health departments were waged in 1946 is evidenced by the fact that in 15 of the 18 counties, more than two-thirds of the persons voting on the proposal voted in favor of the establishment of health departments. In 7 of the counties, the proportion of favorable votes rose to 80 per cent.

The technique employed in Illinois should receive serious consideration by the health officials and the voluntary health organizations of other states. It is

often possible to secure the passage of any particular item of health legislation very easily by direct personal contact with a few influential members of the legislature. The establishment of local health units under a state enabling act, however, requires local as well as state action, and the maintenance of such units after they are established demands a wide basis of informed public support. John Simon in commenting on Edwin Chadwick's zealous—but not always judicious—efforts to promote the cause of public health a century ago says, "He could not advisedly have thought it possible to snatch his verdict and to revolutionize national habits by surprise," and adds that "He perhaps did not sufficiently recognize that the case was one in which deliberate national consents had to be obtained, and in which therefore no real, no permanent, success could be won, except in proportion as the people and their representative bodies should have made way in a necessarily gradual process of education."

The development of widely-based popular support such as that provided by the State-wide Public Health Committee of Illinois is no easy task; but it is, in the long run, the surest and safest road to the Promised Land.

THE STAFF OF LIFE

AT the 73rd Annual Meeting of the Association, two years ago, the following resolution was unanimously adopted:

WHEREAS, the order of the War Food Administrator making compulsory the enrichment of white bread and rolls, the legislative action of certain states with regard to enrichment of certain staple foodstuffs, and the voluntary action of many food industries have resulted in an improvement in the national dietary with respect to several highly essential nutrient elements, and

WHEREAS, this enrichment in staple low cost foods has been of proportionately greater benefit to the economic groups whose diet is most in need of betterment, and

WHEREAS, the federal order for enrichment of white bread and rolls will terminate with the passing of the war emergency, be it

RESOLVED that the American Public Health Association goes on record as favoring appropriate state and federal action to perpetuate the benefits that have accrued to the national dietary through enrichment of staple foods in accordance with the recommendations of the National Research Council.

The contemplated emergency has arisen. The federal regulations which have proved so valuable are now no longer in existence; and it is of vital moment that state legislation should be enacted as promptly as possible to fill the vacuum. The need for action is particularly pressing in the case of flour.

The particular form which a state law should take must be determined by local conditions; and, in several instances, the state health commissioners of neighboring states have discussed the problem during the past few months. The problem can be best met either by adoption of the model act proposed by the Council of State Governments, or by an act requiring that flour and bread (or, perhaps, all foods) sold in the state must conform to the standards set by the Federal Food and Drug Administration for enriched flour (or other foods). In any case, a single standard of enrichment on a country-wide basis is essential.

We urge upon the state health departments of all our states that they give serious consideration to this question and submit appropriate bills for the consideration of their respective legislatures during the 1947 sessions.

Credit Lines

ADVERTISING METHODS IN RECRUITMENT

Among the papers presented on the program of the Merit System Unit at the 74th Annual Meeting in Cleveland in November was one by Richard Wm. Wallen, Ph.D., of Western Reserve's Personnel Research Institute. His title was "The Adaptation of Modern Advertising Methods to the Recruitment of Personnel." A summary of his paper, prepared for Credit Lines, follows:

Psychology, with its interest in the problems of human beings has much to contribute toward building up the kind of public health department public health people want. Sinking his voice to a murmur, Dr. Wallen mumbled, "The American Public Health Association is giving away diamonds at the end of the meeting." Everyone in the audience craned forward, unable to catch his words. Then he shouted the same sentence, citing the first performance as an example of our failure to reach people with our message. The American Public Health Association *has* diamonds—jobs in public health—to give away, but in offering positions of real opportunity and service, we are mumbling and failing to attract the finest quality of personnel.

He then asked the audience to list three pairs of A's standing for: Aiming Advertising, Attracting Attention, Appealing to the Applicant.

Aiming Advertising—A true fisherman determines the kind of fish he wants to catch, seeks out the places where they are, suits his rod, line, and bait to the fish's taste, and then angles with patience and skill. "Where are the skilled physicians and nurses you want to attract to your jobs?" It is necessary to aim advertising at the time and place where prospective staff members are. Quoting Dr. Wallen: "You don't use *Colliers* but the *Journal of the American Public Health Association*. What about schools and colleges, training centers, representing reservoirs of public health power? Are you at the level of people in training? Do not waste time on a shot-gun attack if a rifle will do better."

Attracting Attention—We need to make people turn their heads and look at the announcements in the recruitment program. The tone of general advertising must be watched.

It may be a chatty letter to a group of girls in training or a dignified letter to physicians, but all factors must operate within the framework. Nobody cares about a simple announcement of "positions open"—everyone is interested in his own life and the things he's going to get out of it. The heading must stand alone. Pictures are said to be worth a million words. Interesting pictures in public health work will make people read. Recruiting material must arouse emotional not purely academic interest. Color helps. The staid physician may not glance at something that looks like an advertising blurb, but an unusual color presents interest. "Try to follow the fish's thoughts as you dangle the hook!"

Out of sight is out of mind. An idea must be kept before the people you are trying to attract, and repeated. Out of thousands who go to college many would be good for public health work, but neither you nor they know it unless they have heard favorably of public health before they get training. An individual might want the chance six months from now that he spurns today; so you have to keep the chance there.

Timeliness is very important. As an example, Dr. Wallen recalled an effective sign near the ferries which go to New Jersey, and which commuters could see on their way home to Jersey at night. "If you lived in London Terrace, you would be home now!"

Appointments should be made into news items; tell about the people taking the jobs; make their communities proud of them. There are hundreds of human interest stories concealed in the files of the health departments the country over. They would make timely magazine articles—human interest material. "Articles in magazines help sensitize the public to the need for well trained people, and as Dr. Racker pointed out, get to your students."

Appealing to the Applicant—Appealing to the applicants is the heart of modern advertising. Do you want to go out with lassoes and butterfly nets to get people to take examinations, or do you want them to come to you as flies crawl over sugar. Provide the sugar.

There are four motives which activate most people and which may be described as the four S's. 1. Salary. In your field salary is not very high, so something else must be emphasized. 2. Status. People want prestige and recognition. They want a place

in the community, and professional opportunity for original and creative thought. They want something they can be proud of. 3. Security. People work for a shield against the years. If you can offer security as well as a job to be well done, you have a powerful appeal to people who are not sure whether their jobs in private industry will last. 4. Service. Perhaps this is a sentimental motive, but young people in training genuinely want to be of service. The poster notice of job opportunities doesn't show this. Make it live in sentences and phrases.

There is need for research in your field. You do not know what attracts people into public health work. You might learn through questionnaires. Find out also why people stay away. A study of the attitudes toward and information about public health of the people in training will tell you what they think and know about public health. I have heard of people who are members of the American Public Health Association and don't even know it.

Make it easy for applicants to respond to an appeal. The message should be short and memorable. Supply penny postcards on which interested people may write to you for more details. See that the hours when you can see applicants suit the hours when people can come. People who are working on another job can't get away between 9 and 4:30, so you need hours in the late afternoon or evening.

Letters should be written by electric typewriter and signed in ink to look genuine. A card saying, "I am interested in your announcements of" with ample space for name and address, should accompany the letter describing the position. After that it's a matter of selling.

Tell what health service does for people and how it can increase their satisfaction in living.

The problem is not complicated, but it requires work. I have tried to make this audience feel the problem emotionally in order to get action on it.

VERMONT STATE HEALTH COUNCIL

As late as July, 1946, there were no local health departments in charge of full-time medical officers in the entire State of Vermont, a situation in which this state was unique among the 48 states. That this is not to be a continuing condition is indicated by the formation of the Vermont State Health Council late in 1946. Made up of representatives of 29 organizations interested in health problems, the council was organized under the sponsorship of the Vermont State Medical Society. The Chairman of the Council is Frank C. Angell, M.D., of Randolph, and John W. Brownlee of Rutland, President and Executive Secretary, respectively, of the Vermont Medical Society. Among those serving on the Executive Committee is Robert B. Aiken, M.D., Acting Secretary and Executive Officer of the State Health Department.

The State Health Council is an outgrowth of Governor Proctor's Health Plan developed by a Health Advisory Committee appointed in 1945. By the middle of 1946 it had adopted a 22 point

health program, many principles of which are embodied in the Constitution of the newly formed Health Council.

Included in the governor's health plan is a recommendation for the organization of the state into five health districts to cover the entire state and the establishment of health centers in appropriate rural areas. The district staff would include, as a minimum, a full-time health officer, a secretary, and a staff of nurses. The districting of the state proposed in Dr. Haven Emerson's *Local Health Units for the Nation* is included in the governor's plan with only minor changes. The governor further points out that Dr. Emerson's recommendation that "all phases of health work be headed up in these districts . . . may be an answer to the proper organization in the state for the improvement of health." Among the purposes of the new council is "extending the physical facilities of health to the point where complete coverage becomes possible for all people in the state of whatever status wherever located."

Among other recommendations, in-

cluded also in the Council's Constitution, are coördination of health facilities in departments of health, welfare, and education; an adequate building for the State Health Department, the establishment of local health councils, a Division of Nutrition in the State Health Department, and adequate programs for the control of tuberculosis and of Bang's disease.

MISSISSIPPI BEGINS TO CUT ITS RURAL DOCTOR SHORTAGE

According to a special tabulation for the year 1941 made by the U. S. Public Health Service, Mississippi ranked lowest among the 48 states in the ratio of practising physicians to population. At that time there was in the state only one practising doctor for every 1,700 persons, whereas in the United States as a whole there was an average of one for approximately 800 persons.

These figures give point to a recent announcement by the Mississippi State Medical Education Board that 47 new doctors will come to Mississippi in the next 5 years. Charged with the administration of the program by the 1946 Legislature, the board has granted 47 scholarship loans effective for the first semester of 1946-1947. The students awarded the scholarships have signed contracts to practise in rural Mississippi upon completion of medical education and internship.

The 47 students are attending 11 different medical schools throughout the nation, 30 of them in Mississippi's two medical schools. They come from 28 towns in 23 counties of the state; more than half of them from towns of less than 4,000 population. They include 21 World War II veterans, 6 women, and 4 Negroes.

PHILADELPHIA VISITING NURSE ANNUAL REPORT

That Little Black Bag with its picture on the leaflet title page is the

spring board for the annual report of the Visiting Nurse Society of Philadelphia. A chatty story on what the bag contains and what services are rendered by the nurses who carry it, illustrated with line drawings in red, leads up to service statistics, financial statement, and important names. All in all an effective report that tells a lot with little expenditure of words or paper.

INFLUENZA VACCINE STUDIES IN ILLINOIS

Students at the University of Illinois, Northwestern University, and two state normal schools are being offered influenza vaccine on a voluntary basis. A comparison of the incidence of the disease in those who accept the vaccination and those who do not will be made to help in establishing the effectiveness of the vaccine. The Illinois State Department of Health is making the study possible by furnishing the vaccine without charge.

MINNESOTA STUDIES THE AGING PROCESS

Under an experiment conducted by Ancel B. Keys, Ph.D., the University of Minnesota's Laboratory of Physiological Hygiene will study the aging process. Half of the 400 voluntary "guinea pigs" will be university students between 18 and 20 years and the other half men between 45 and 60.

CURED CANCER CLUB

A new type of cancer education has been developed by the Queens County (New York) Cancer Committee of the American Cancer Society. Its first member, cured of cancer seven years ago, was selected in August, 1946. Membership is open to Queens persons who have been cured for five years or more. There is also provision for auxiliary membership for those cured for less than five years.

In addition to serving as an incentive

to make people realize that cancer is curable, it is also hoped to gain information on the number of persons in Queens who have been cured of the disease.

Coöperating with the Queens Committee is the New York City Department of Hospitals. Dr. Leonard Goldman, director of the department's free cancer detection and prevention clinic at Queens General Hospital, supervised the organization of the club.

MEDICAL CARE FOR FAMILIES OF YALE STUDENT VETERANS

Yale University now provides medical care for dependents of veterans enrolled as students in the university. Both clinical and home medical services are provided at nominal fees through a panel of physicians to which patients are referred by the university department of health. Clinic service is provided by the Grace-New Haven Community Hospital for standard clinic fees. Maternity cases are cared for at the Prenatal Clinic, hospitalization is provided by the Grace-New Haven Hospital.

PARENTS OF SPASTIC CHILDREN FORM ADVISORY COUNCIL

Late in 1946 a National Advisory Council composed solely of parents of spastic children was formed under the auspices of the National Society for Crippled Children and Adults. This Council will work at the Chicago Headquarters of the Society and through member groups in the 48 states. The parents will make recommendations for the location of clinics, nursery schools, training centers and rehabilitation centers for spastic children.

LITERATURE AVAILABLE ON MILK AND OTHER FOODS

The U. S. Public Health Service under date of October, 1946, has prepared a "List of Publications of Milk and Food Section." The items listed are

those available without charge from the Milk and Food Section, Sanitary Engineering Division, or the Publications Section, U. S. Public Health Service, and those for sale by the Superintendent of Documents, Government Printing Office, Washington 25, D. C.

The list includes the "Milk Ordinance and Code," and similar codes and reports of the U. S. Public Health Service as well as reprints from *Public Health Reports* and from technical journals and popular magazines. Copies of the List may be obtained free of charge from the Milk Section, Sanitary Engineering Division, U. S. Public Health Service, Washington 25, D. C.

DISABLED VETERANS NOT VOCATIONALLY HANDICAPPED

Two news items about disabled veterans are passed on to our readers. First is the reënlistment by the Army of disabled veterans. The Army opened its ranks to this group on the plea of a 29 year old former Air Force master sergeant who lost his left forearm in Pacific combat. It is expected that about 5,000 disabled veterans will re-enlist. National Commander Griffith of the American Legion commended the War Department and suggested that other branches of the armed services follow suit.

The other news is of movies about the disabled veteran. The Office of Vocational Rehabilitation, Federal Security Agency, in December released "Come-back" for non-theatrical showing to employer groups throughout the country. It demonstrates that a disabled person, properly trained for work and placed in the proper job, is no longer vocationally handicapped. Among the scenes are the successful battle against disabilities waged by Jane Froman, Al Capp, Bill Stern, and Tami Mauriello, among others. The film was made with the coöperation of the Bulova Watch Company, Caterpillar Tractor Company,

Ford Motor Company, and Western Electric Company, all of which are successful employers of handicapped persons.

In releasing news of the film, Michael J. Shortley, Director of the Office of Vocational Rehabilitation said, "If the million still waiting for rehabilitation were to make approximately as good a showing as was actually achieved by the 36,000 who returned to jobs last year, their contribution to the wealth of the nation would approximate two billion dollars a year. In many cases the income tax paid by a rehabilitated worker in a single year would more than offset the entire cost of the services extended to him."

The American Legion is also showing its film, "No Help Wanted," a factual presentation of the employment capabilities of the disabled.

CANNING SAFEGUARDS AGAINST BOTULISM

The Bureau of Human Nutrition and Home Economics of the U. S. Department of Agriculture has completed a three year intensive laboratory research on home canning of low acid foods (meat and practically all vegetables). The amount of heat it takes to kill highly heat resistant organisms in low-acid vegetables and meats has been put to careful test. The results provide new evidence that steam pressure is the only way to can this class of foods in home kitchens. But it is now recommended that steam processing time can be from 25 to 50 per cent shorter than was earlier thought possible for vegetables in pint glass jars and for some in quart jars.

The results of the research have been published in U. S. Department of Agriculture *Technical Bulletin* No. 930 "Home Canning Processes for Low-Acid Foods Developed on the Basis of Heat Penetration and Inoculated Packs." This is available from the

Superintendent of Documents, Washington, D. C., at 10 cents a copy.

FLORIDA WANTS LOCAL HEALTH UNITS

The Credit Lines editor recently had occasion to look through the files of state health department bulletins. He found that *Florida Health Notes* has been engaged in a campaign of making Floridians "local health unit-conscious," and telling them of the state's unmet health needs.

The March issue, for example, points out the need for more adequate local health department buildings and equipment, and quotes the testimony of Dr. Atwater for the Association before the Senate Committee on Bill S 191 that less than 10 per cent of the health departments of the country are provided with physical facilities even approaching standards of adequacy.

The May issue describes a local health unit fully, tells how one is made possible by Florida law, and gives the procedure for organizing one. Each local health unit activity is described and illustrated with photographs from actual operating units.

August is devoted to Florida's Public Health Problems and what is needed to combat them. "The first and most essential need is the completion of an efficient organization covering the entire state—a full-time health department in every county." One by one the problems are outlined in words and pictures—malnutrition, hookworm, tuberculosis, and many others.

THE WISCONSIN CRUSADER IS NOW PICTORIAL

The Crusader of the Wisconsin Anti-Tuberculosis Association (Health Service Building, Milwaukee 2) went pictorial with the September, 1946, issue. Its editor, Harold Holand, sends Credit Lines the last four issues of 1946. He believes it to be "the first such publication to concentrate on photographic

rather than textual presentation." It has many ideas worth study by other editors of health education publications. It continues to be on good paper and attractively done in color, chiefly clear-cut red and black. One sour note to the editor: The foggy blue-Monday blue of the November issue "pleaseth us not."

ALMANAC FOR HEALTH EDUCATION

The almanac is the most thumbed book in the great farm regions of the Middle West. Building on this, Nina Lamkin, Director of Public Health Education in the Nebraska State Health Department, has prepared a 1947 Almanac "For Better Health in Nebraska." It has the paper and typography of the traditional almanac as well as historical notes on the days of the year, notes on the sun and the moon. But its limericks, its epigrams, pictures, questions and answers are all related to health. The sum total is a story of what services the State Health Department provides, why there should be local health departments, and what they can do for a community, and simple summaries of health matters—the Rh factor, chest x-rays, school health, and many others. It is an excellent piece of grass roots health education. The Almanac doesn't say so, but we assume the editor (State Capitol, Lincoln, Neb.) would be proud to share it with you.

TEACHER AIDS IN KEEPING CHILDREN WELL

In August (p. 903) we reported the Film Strip, "Teacher Observations of School Children." Since then the Metropolitan Life Insurance Company has issued a supplementary booklet "What Teachers See," containing many of the pictures (in excellent color) shown in the film and explaining more fully how to recognize a healthy appearance in children as well as signs indicating departures from it. The film and

its accompanying booklet are considered in the nature of an experiment, which, if successful may lead to preparation and distribution of similar visual aids for teachers and parents. The Film Strip is available for loan from the Metropolitan Life Insurance Company, 1 Madison Avenue, New York 10, N. Y., and is accompanied by the supplementary material.

TROUBLE AHEAD FOR ANTIVIVISECTIONISTS

Credit Lines has already noted the organization of the National Society for Medical Research (September, 1946, p. 1062). Our December mail shows that this is more than a paper organization. It sends us an information bulletin on happenings in the anti-vivisection world the country over—and even beyond. It also sends a financial and activity report made to the Association of American Medical Colleges under whose auspices it is organized. Other items include "What Value Animal Experimentation," by Harold C. O. Holck, Ph.D., and Edwin D. Lyman, M.D., reprinted from the *American Journal of Pharmaceutical Education*; "Are Animal Experiments Needed?" by S. C. Ivy and S. F. Zobel, reprinted from the *Journal of the American Pharmaceutical Association*; "Operation X—Survival," by Albert Q. Maisel, reprinted from *Readers Digest* and condensed from *Hygeia*, and finally a "Pledge for Antivivisectionists" (author not reported). Presumably all of these items are yours for the asking from the National Society for Medical Research, 25 E. Washington St., Chicago 2, Ill.

The pledge we give you in full:

I am unequivocally opposed to experimentation on animals in medical research. In protest against this practice I pledge myself and my children to refrain from making use of any of the knowledge gained through research in which animals were used:

1. I shall examine with extreme suspicion all medical knowledge.
2. If I or my children become diabetic I shall not use insulin.
3. If I am afflicted with pernicious anemia I shall not use liver extract.
4. I shall never accept a blood transfusion.
5. Vitamins will be as poison to me.
6. I shall use no drugs which have first been tested on animals for strength and purity.
7. If an operation is necessary I shall repudiate anesthesia.
8. These operations shall be anathema to me and mine—
 - a. On the heart and its valves
 - b. On the lungs
 - c. On the blood vessels
 - d. On the brain
 - e. On the stomach and intestines
 - f. On the ovaries and womb
9. If my child is afflicted with rickets I shall look away in pity.
10. I shall not allow my children to be immunized against diphtheria but shall allow them to strangle with this disease.
11. I shall avoid sulpha drugs and penicillin as I would the plague.*
12. I shall make out my will immediately.

Signed

* A definite policy on the plague will be announced later.

HERMANN M. BIGGS AND THE HEALTH CENTER IDEA

Few public health workers are much concerned with the historical background of their subject and it is only seldom that items of special public health interest appear in the *Bulletin of the History of Medicine*.

The October, 1946, number (Volume XX, No. 3, pp. 387-412) contains an excellent article by Milton Terris, M.D., M.P.H., of Bethesda, Md., on "Hermann M. Biggs' Contribution to the Modern Concept of the Health Center." Dr. Terris believes that the outstanding

contribution to the development of the modern concept of the health center in the United States was made by Dr. Hermann M. Biggs of New York State more than twenty-five years ago. It was brought into sharp relief by the influenza epidemic of 1918 which focused attention on the serious shortage of medical personnel and facilities in the rural sections of New York State.

This well documented review assembles significant information which ought to be accessible to all, and it includes the original memorandum on health centers proposing a bill authorizing a county, city, or consolidated health district to create and maintain one or more health centers with the assistance of state aid.

CHAMBER OF COMMERCE SUGGESTS HEALTH MEASURES

The Health Advisory Council of the U. S. Chamber of Commerce recently sent to its local chambers suggested news releases adapted for local health committee uses. Two included the recommendations of the American Public Health Association, as given in *Control of Communicable Diseases* on the common cold and influenza; another pointed out the community and dollar dividends resulting from adequate public health expenditures; and another, designed especially for areas with small industrial plants, suggested a joint industrial health plan covering several small plants. Properly used by local communities these represent a significant widening of health education influence.

The Chamber has also issued a recent summary on How Chambers of Commerce Are Attacking on the Health Front. This summarizes, by way of illustration, activities of some of the local chambers in furthering the health work of their communities.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted. All books reviewed in these columns may be purchased through the Book Service.

Five Million Patients—By Allen W. Freeman, M.D. New York: Scribners, 1946. 299 pp. Price, \$3.00.

Straight forward, systematic, common sense, personal modesty, professional pride, or at least deep satisfaction; such are the words that come to the tongue or pen while reading this matter-of-fact autobiography of our friend from student to professor. One would not look for embroidery in the texture of so simple a tale of a characteristic life, and one finds none. Its beauty of pattern and the simplicity of its philosophy call for more of the embellishments of stories written to sell.

In the three hundred pages we find a narrative in episodes "as true as the author can make it." Each of the one hundred and eleven glimpses into the happenings of forty-five years is so brief as to leave the reader always with an appetite for more. We join the student as he enters his medical school and share his progress of hard work through fifteen illustrations of a well established academic discipline until he has earned his medical degree. The apprentice, as he nominates his rôle for three years, takes us with twenty hops through hospital and into practical public epidemiology. Book III gives us fifty micro-photos of The Journeyman while he moves swiftly over the thirteen years that make him a national leader in administrative experience and give him the length, breadth, and depth of public health that prepared him for the next leap ahead. In the fourth book there are twenty-six views of The Professor at home and abroad from 1921 to 1945.

Five million is a good round figure for home folks, but the patients or per-

haps the clients of such a servant of the sciences of preventive medicine and of civil government, their necessary partner, are not to be counted in so modest a seven numbers.

Allen Freeman is the same in print as in action and in human relations. He has once again put us all in his debt. If we incline to complain it is of the matters within his years which he has passed over without remark. In his writing, as in the way of his work, he has shown how he is strong in the reserves he does not make public, in the resources he decides to hold for another occasion.

A man of industry, disciplined by origin, by education, by his profession and by his innumerable contacts in all walks of life. A life is here recorded for the pleasure and serious thought of a host of readers, doctors and patients.

HAVEN EMERSON

The Control of Venereal Disease—By R. D. Vonderlehr, M.D., and J. R. Heller, Jr., M.D. New York: Reynal & Hitchcock, 1946. 246 pp. Price, \$2.75.

This volume presents in non-technical language for the general reader a report to the nation of the origin and progress and present status of venereal disease control in the United States.

Here will be found things that the public should know: the tremendous interest aroused during the first world war; the long period of apathy until the problem was again forcibly brought to light by the Surgeon General of the United States Public Health Service; the progress made in venereal disease control from the reawakening to the

outbreak of the second world war; the importance of the repression of prostitution and prevention of juvenile delinquency; and the value of coördinated activities of allied agencies in presenting a solid front against the venereal diseases.

The discussions on prostitution and juvenile delinquency, and of psychologic and psychiatric aspects of the venereal diseases deserve special mention. Prior to the recent war, venereal disease programs were directed almost entirely to standard medical and public health practices, without reference to the moral side of the problem. Experience during the war showed conclusively that venereal diseases cannot be controlled by medical measures alone in the face of increasing sexual promiscuity. The importance of determining behavior patterns as a guide to venereal disease control activities is clearly shown in the chapter on Venus and Psyche.

It is predicted that, unfortunately, this book will not be widely read by the public. It behooves those engaged in public health work to transmit its message. As a source of material and methods for its presentation to the lay public, the health officer will find this volume very useful.

WILLIAM A. BRUMFIELD, JR.

Eye Health—A Teaching Handbook for Nurses—*Published by The National Society for the Prevention of Blindness, Inc.*, 1946. 108 pp. Price, \$.60.

The book is "designed to provide the nursing profession with background information on aspects of eye health." In a readable style it gives a compact review of useful data ranging from the structure of the eyes through eye health in childhood and adult ages to suggested teaching opportunities for the nurse.

The format follows one of the rules for maintaining eye health by using dull-finished cream-tinted paper, wide page

margins, plain sharp-edged type of proper size and spacing. The cross references and index, as well as the brief annotated bibliography are helpful to the reader.

This book should be of interest to nurses in all phases of community service.

KATHERINE E. PAYNE

Psychiatric Interviews with Children—*By Helen Leland Witmer. New York: Commonwealth Fund*, 1946. 443 pp. Price, \$4.50.

This volume is addressed to the students of psychotherapy of children and to practitioners of child psychiatry, but it can be read with profit by many others, including physicians, nurses, teachers, and parents. The methods used in child guidance clinics have never been well understood by those not directly concerned. Yet it is important that the doctor and the teacher and the nurse who come first into contact with children needing specialized attention should understand at least the background technics and be able to select cases wisely for referral.

These ten case records from eight different clinics will serve the public-health professions and doubtless be of interest as well to the specialists in this field, for there are several schools of thought represented. Beside the case reports Dr. Witmer, who comes from the Smith College School for Social Work, describes the general content of psychotherapy in child guidance clinics. Each therapist reporting here has "attempted to show the significant words and actions, and the reasons underlying them, by which he and his patient worked through to a satisfactory solution of the problems that brought the child to the clinic. In this process the therapists were usually assisted by psychiatric social workers, for it is the child guidance assumption that most psychiatric problems in children represent a maladjustment in family life. A child, these

practitioners believe, can rarely be helped unless the parents achieve a new orientation toward him, one that supports him in his efforts to relate himself to people more satisfactorily than before." It is the working out of this conception of psychiatric treatment that is demonstrated in the case records in this book. The volume is easy to read and well worth the effort. It takes some of the mystery out of child guidance and suggests that the therapists have a normal supply of common sense.

REGINALD M. ATWATER

Food Values of Portions Commonly Used—By *Anna dePlanter Bowes and Charles F. Church, M.D.* (6th ed.) Philadelphia: College Offset Press, 1946. 58 pp. Price, \$1.60.

The purpose of this book is to supply authoritative data on food values to workers in the fields of medicine, dentistry, dental hygiene, public health nursing, and nutrition. A distinctive feature of the book is its well organized, readily available information on commonly used portions of a large variety of foods.

The fact that this booklet has gone through six revisions in nine years testifies to its wide acceptance and use by professional group leaders. Important changes in the new edition are: all food tables rewritten; staple foods of other countries added; recipes for all prepared foods recalculated to include new food values of ingredients.

ETHEL AUSTIN MARTIN

Insight and Personality Adjustment—By *Therese Benedek, M.D.* New York: Ronald Press, 1946. 301 pp. Price, \$4.00.

The psychoanalysts seem to be emerging from their darkened consultation rooms to have a look at sociological problems. The author of this book, who is a member of the Institute of Psychoanalysis in Chicago, has been stimu-

lated to study the problems of a war-time society as they affect the individual who is involved in that war.

Dr. Benedek's book is about the psychological influences of war upon the soldier, veteran, his wife and family. She has described admirably the psychological trauma inflicted upon the wife and family of the soldier but has drawn on meager data to cover the problems of the soldier. Perhaps this part of the story should have been left to those who were more intimately associated with psychiatric work of the Army and Navy medical services. Unfortunately, the emotional problems of the many men who were classified as "militarily unsuitable" and other 4 F's were not discussed in the book. The author's analysis of family problems arising from the war's impact is vivid but somewhat depressing. The reader is left to find his only solace in the realization that so many of our veterans have penetrated successfully the emotional pitfalls of war and are now making such good adjustment in the post-war world.

CHARLES E. SHEPARD

The Fever Bark Tree—By *M. L. Duran-Reynals.* New York: Doubleday, 1946. 274 pp. Price, \$2.75.

The Fever Bark Tree is a historical chronological record of the discovery of the bark of the cinchona tree and its development in the treatment of malaria. The period covered is that from the romantic time of the Spanish Dons and their laden galleons down to the present day, with the Indians and their gods guarding those stately trees, a vital and picturesque element of the pageant.

Built upon the framework of the record of medical, botanical, religious, and industrial endeavor, the author has presented to her readers in an interesting manner the interrelationship of the drug's discovery to human frailties and virtues existent throughout the ages.

Intrigue, ignorance, humanitarianism, quackery, loyalty, philanthropy, religion, and intransigence are portrayed vividly in their rôle in the drama of the drug's turbulent development.

Documented with a special section on bibliography, the book should serve as an additional source of reference to clarify many previous, apparently erroneous legends.

It is perhaps regrettable, from the standpoint of the lay reader, whether through intention or not, that the rôle of quinine as a suppressive measure against symptoms and as a curative agent is not accentuated in contradistinction to its lack of potency in killing the form of the parasite as injected into man by the anopheline mosquito.

JOHN E. ELMENDORF

Body Mechanics in Nursing Arts
—By *Bernice Fash*. New York: McGraw-Hill, 1946. 130 pp. Price, \$2.75.

This is a most welcome little handbook for quick reference. The first section introduces individual tests of principles in body mechanics and the demonstration sketches are excellent; they are understandable even for the novice.

Section two deals with specialized nursing skills under improved work habits. These reduce fatigue factors, often so pronounced in the midst of a thousand and one things the nurse is called upon to do.

Valuable also are the chapters on body mechanics of the business and plant worker. They offer a wider scope of teaching material for the health educator and should benefit the nurse who has to give much of her time to clinical instruction. The generous use of illustrations is most commendable.

This manual should be a welcome accessory in any nursing library and for any branch of nursing. However, it should not replace the textbooks on nursing skill, which give greater tech-

nical detail, but it does contain material which is scientific and concise.

LOUISE L. ROEDER

Cancer Can Be Cured—By *Alfred J. Cantor, M.D.* New York: Didier, Publishers, 1946. 175 pp. Price, \$2.50.

This volume is a short treatise on the prevention and curability of cancer for lay readers. Much of its information is sound, but occasionally an unproved hypothesis has been advanced as an accepted fact, and in some parts of the book there is a tendency toward over-emphasis. The book is easy to read but inclined toward the dramatic. Absurd suggestions are interspersed with sound statements. For example, the admonition to consult a physician at least yearly for a thorough examination does not seem to have the same tenor as the advice to protect yourself from tobacco smoke by tearing cigarettes, cigars, and pipes from those individuals near you who are smoking.

The book is too elementary for physicians and public health workers. It is written from too emotional a viewpoint for the analytical layman. It may be well received by that part of the public which enjoys graphic and emotional presentations, and among this group lives may be saved.

HERBERT L. LOMBARD

Greenwich (Conn.) Community Program "Eat a Good Breakfast" Campaign—*Greenwich Nutrition Committee. Greenwich, Conn.: Greenwich Tuberculosis and Health Assoc., 1946. 124 pp.*

This report of a community nutrition project conducted at Greenwich, Conn., includes the details of every step in the campaign; pictures of local committees, participating groups and numerous exhibits along with samples of all the posters and pamphlets used, replicas of newspaper publicity, letters soliciting

coöperative action and letters received. Few of the ideas are new, but the report shows how good ideas from many sources may be used by community agencies coöperating to promote such a health project.

The publication would seem to be of primary interest to the local community where the project was undertaken with its obvious purpose that of giving credit to local effort. It might serve as a guide to another community wishing to undertake a similar project.

HELEN S. MITCHELL

Practical Malariology—By *Paul F. Russell, M.D., Luther S. West, Ph.D., and Reginald D. Manwell, Sc.D.* Philadelphia: Saunders, 1946. 684 pp. Price, \$8.00.

This book is a well balanced presentation of its subject, and will be an indispensable tool for all who work in its special field and related subjects. The medical, entomological, and engineering phases of the disease and its control are admirably handled within the limits of a single text.

Chapters 6 and 7 on the morphology and bionomics of mosquitoes are exceptionally good. In Chapter 8, on the Distribution of Anophelines, the tables of important vector species, while good, probably contain some minor errors, e.g., in the table on page 188 it is doubtful that *A. labranchiae atroparvus* occurs in Japan. Chapters 16, 17, and 18 on the epidemiology of malaria are the best presentations this writer has seen since L. W. Hackett's classic.

In Chapter 22 on Larvicides, a fuller treatment of emulsifiers would have been helpful to field control personnel. In Chapter 25 on Control of Adult Mosquitoes (at pp. 523-525) a more complete treatment of DDT residual would have been desirable. This new effective adulticide is radically changing our ideas as to methods of control of both culicine and anopheline species.

In Chapter 26, the importance of educational measures would justify a considerable expansion of this section (pp. 541-545) and its segregation into a separate chapter.

The entomological keys in the Appendix are excellent of their type, but occupy 71 pages. Diagrammatic or pictorial keys of the type developed by the Malaria Control in War Areas unit of the U. S. Public Health Service would have been equally exact and more clear and compact than the conventional type of taxonomic key.

The typography and format of the book are unusually good, the numerous photographic illustrations are exceptionally clear and well selected, and the line drawings excellent.

The dedication of the book to the malaria control organizations of our armed forces in World War II is a well deserved tribute to a fine group of unsung heroes.

H. F. GRAY

Industrial Toxicology—By *Alice Hamilton and Rutherford T. Johnstone.* New York: Oxford University Press, 1945. 72 pp. Price, \$3.50.

In this day of elaborate treatises reaching encyclopedic proportions, many practitioners and specialists in the field of industrial health will welcome this refreshingly concise summary of the pathology, diagnosis, treatment, and prevention of occupational diseases. Dr. Hamilton presents pathology and diagnosis in Part I, and Dr. Johnstone discusses treatment and prevention in Part II. Part III is a bibliography of 352 items.

Of special interest to this reviewer is the statement: "It should be reiterated constantly that the primary treatment is prevention." Recommendations for preventing occupational diseases are generally sound and practical, but the authors are tempted at certain points to be overly specific on engineering details.

Readers will appreciate the care with which the authors have studied the amassing literature in this field, and the way in which they have recorded their experienced judgment on significant developments.

WILLIAM N. WITHERIDGE

Manual for School and Institutional Lunch Rooms (revised)—*Ohio Dietetic Association. Cleveland: Ohio Dietetic Association, 1946. 222 pp. Price, \$2.00 (\$1.85 for 3 or more).*

This is a revision of *Manual for Managers of Rural and Other Small School Lunch Rooms*, reviewed in this *Journal*, Vol. 32 (Aug.), 1942, p. 881. The name was changed because the material is valuable for use in urban institutions and schools, as well as in rural schools. The material is uniquely suited to fit the needs of the untrained workers, who, more times than not, are respon-

sible for the food service in schools and child caring institutions.

The untrained worker will find the general information preceding the recipe section very helpful—this includes a table of miscellaneous equivalents of weights and measures, some common food measurements, the average number of servings obtained from common staples, and information on the use of dehydrated milk solids.

Simple directions and suggested forms for cost accounting are included. The section on *Location of Lunchroom* includes floor plans for use in school buildings where expansion is impossible.

The section on *Equipment* has been revised and a few new recipes have been added.

This might well be used as the standard manual in school systems that do not have manuals of their own.

ALICE H. SMITH

BOOKS RECEIVED

Listing in this column acknowledges the receipt of books and our appreciation to the senders. Space and the interests of readers will permit review of some, but not all, of the books listed.

AGING SUCCESSFULLY. By George Lawton. New York: Columbia University Press, 1946. 266 pp. Price, \$2.75.

CHILDREN IN THE COMMUNITY (The St. Paul Experiment in Child Welfare). By Sybil A. Stone, Elsa Castendyck, and Harold B. Hanson, M.D. Washington: Gov. Ptg. Office, 1946. 182 pp. Price, \$35.

COMMUNITY CENTERS AS LIVING WAR MEMORIALS. By James Dahir. New York: Russell Sage Foundation, 1946. 63 pp. Price, \$50.

CONTROL OF RINGWORM OF THE SCALP AMONG SCHOOL CHILDREN IN HAGRESTOWN, MARYLAND, 1944-45. By Louis Schwartz, *et al.* Washington: Gov. Ptg. Office, 1946. 27 pp. Price, \$10.

THE COST OF SLUMS IN NEWARK. By Jay Rumney, Ph.D., and Sara Shuman, M.A. Newark, N. J.: Housing Authority of City of Newark, 1946. 36 pp.

DDT AND THE INSECT PROBLEM. By James C. Leary, *et al.* New York: McGraw-Hill, 1946. 176 pp. Price, \$2.50.

DESIGN FOR SAFE LIVING. New York State Department of Health. New York: Reinhold Publishing Corp., 1946. 16 pp.

DEVIL BY THE TAIL. By Langston Moffett. Philadelphia: Lippincott, 1946. 431 pp. Price, \$3.00.

THE DUKE ENDOWMENT YEARBOOK No. 14. The Duke Endowment. Charlotte, N. C.: The Duke Endowment, 1946. 41 pp.

THE FORCES THAT SHAPE OUR FUTURE. By Clyde Eagleton. New York: New York University Press, 1945. 200 pp. Price, \$3.25.

THE FREEZING PRESERVATION OF FOODS By Donald K. Tressler and Clifford F. Evers. (2nd ed.) New York: Avi Publishing Co., 1946. 932 pp. Price, \$10.00.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Grim Note — Incidence of second-attack poliomyelitis appears to be high enough to cast doubt on the existence of clinical immunity following an attack of the disease. So don't expect acquired immunity alone to protect persons in contact with patients. Health administrators, please note.

BRIDGE, E. M., *et al.* Clinical Immunity in Poliomyelitis. *Am. J. Dis. Child.* 72, 5:501 (Nov.), 1946.

Primitive and Antisocial—Probably there is less than a nickel's worth of really "useful" information for you in this paper, but if you have a normally morbid curiosity you'll find it readable. You'll agree with the author that the person who has none of the listed signs of the psychopathic personality must be a saint. He says that most of us fall somewhere between the psychopath and the saint. How about you?

CASON, H. The Symptoms of the Psychopath. *Pub. Health Rep.* 61, 51:1833 (Dec. 20), 1946.

In Addition to the Mother's Comfort—In comparable groups there were fewer stillbirths and deaths-during-the-first-week among infants born of mothers receiving continuous caudal analgesia than among the controls. If the method could be applied to all deliveries, and with the same results, the present estimated loss of 125,000 viable infants through these causes could be cut in half, the writers suggest.

COLLINS, S. D., *et al.* A Statistical Study of Delivery with Continuous Caudal Analgesia as Compared with Other Methods. *Pub. Health Rep.* 61, 48:1713 (Nov. 29), 1946.

"Epidemical and Other Disorders"

—Just a century ago the first British Medical Officer of Health took office—in Liverpool. The tragic events leading to his appointment and the formidable job he undertook are recounted. This whole story may already be in the history books, for all I know, but if it isn't you may want this reference.

DALEY, A. One Hundred Years—A Retrospect and a Forecast. *Pub. Health.* 60, 2:28 (Nov.), 1946.

We Can Afford the Wastage—In Saskatchewan, all tuberculin negative nurses and other sanatorium personnel were given the benefit of BCG vaccination—a protection we reserve for our red Indians but fail to give exposed professional workers. In Canada, too, the protection, though not perfect, was found to be of the order of 4 or 5 to 1.

FERGUSON, R. G. BCG Vaccination in Hospitals and Sanatoria in Saskatchewan. *Canad. Pub. Health J.* 37, 11:435 (Nov.), 1946.

A Word of Caution—Tuck away these sentences in the card-file of your memory, "It is unwise to send any person to a sanatorium who is merely suspected of having pulmonary tuberculosis. Not until tubercle bacilli are demonstrated should a patient be sent to the sanatorium for treatment." They are from a useful paper reminding health workers what to do with persons with abnormal chest x-rays.

HILLEBOE, H. E., and HOLM, J. Guide for Disposition of Persons with Abnormal Pulmonary Findings on X-Ray Films. *Pub. Health Rep.* 61, 49:1759 (Dec. 6), 1946.

Four Will Do It—Reported here is a study to determine the smallest effective number of topical applications of sodium fluoride. An earlier researcher

had used from 7 to 15 applications. Apparently at least 4 are needed to produce the same benefits.

JORDAN, W. A., *et al.* The Effects of Various Numbers of Topical Applications of Sodium Fluoride. *J. Am. Dent. A.* 33, 21: 1385 (Nov. 1), 1946.

For Kindergartners — Now, it seems, we'll add a "booster" dose of pertussis vaccine to the supplementary diphtheria prophylaxis just before the child starts to school when exposure to whooping cough is greatly increased. Evidence presented lends support to the proposal, at any rate.

KENDRICK, P., *et al.* Re-enforcing or "Booster" Injection of Pertussis Vaccine in Previously Immunized Children of Kindergarten Age. *Am. J. Dis. Child.* 72, 4:382 (Oct.), 1946.

Floating TB Bacilli — Described here are some relatively simple experiments that show tuberculosis to be an air-borne infection and that ultraviolet rays destroy the floating bacilli. There is no reason, concludes the writer, why both ultraviolet radiation and oil treatment of bedclothes and floors should not be used in tuberculosis hospitals. None, except human inertia!

LURIE, M. B. Control of Air-borne Contagion of Tuberculosis. *Am. J. Nursing.* 46, 12:808 (Dec.), 1946.

Not Rules—But Principles—The cook, the plumber, and the lab technician follow rules, but handling people is an art. So says a convention headliner whose paper can be read with benefit by anybody who has one or more people working with, or under, him. That category must include about everyone in the health field but me—and I enjoyed it too.

MAGOUN, F. A. New Ways in Personnel Administration. *Pub. Health Nurs.* 38, 11: 591 (Nov.), 1946.

Boxing the Compass — Every so often, we swing round again to the disuse theory of dental decay. Make

people chew tough meat and tough crusts and all will be well, insists this British proponent of that theory. Disuse, he says, results in decalcification of teeth as it does bones, so he coins the name "disuse odontoporosis" which you may employ without credit if you wish.

NEUMANN, H. H. Food Habits and Dental Caries. *J. Roy. Inst. Pub. Health & Hyg.* 9, 12:373 (Dec.), 1946.

Stirring Times: Challenging Opportunities — Our nation's progress toward solid health administration and the needs yet to be met are briefly told by the one man best situated to see clearly the whole enormously complex problem.

PARRAN, T. National and International Horizons in Health. *Pub. Health Nurs.* 38, 11:583 (Nov.), 1946.

Wise Words of Warning—All persons, before being given influenza vaccine should be tested intradermally for allergy. Profound, and fatal, anaphylaxis is not unknown; that must never be forgotten. What to do in all the varying degrees of reaction to the test is set forth in this paper.

RATNER, B., and UNTRACHT, S. Allergy to Virus and Rickettsial Vaccines. *J.A.M.A.* 132, 15:899 (Dec. 14), 1946.

Hygienic Significance of Dust Laying—A discussant says, "Dr. Smith and his associates know more about coccidioidomycosis than any one else." So, if you want to learn more about the epidemiology of this jaw-breaker than what was covered in a paper on this subject in the December issue of our *Journal*, then this earlier paper should be read too.

SMITH, C. E., *et al.* Effect of Season and Dust Control on Coccidioidomycosis. *J.A.M.A.* 132, 14:833 (Dec. 7), 1946.

A Little of This and That—Hematology, tropical medicine, infectious diseases, endocrinology, virus diseases, among other subjects are skimmed

in an informal, readable, round table. Not to be missed.

STURGIS, C. C., *et al.* Therapeutic "Information Please." J.A.M.A. 132, 16:963 (Dec. 21), 1946.

As Others See Us—"To the British mind the first reaction to some of these (American V.D. publicity stunts) is one of surprise mingled with amusement. On consideration, however, it is readily perceived that it is all the logical pursuance of an accepted line of thought. Venereal disease must be reduced and stamped out."

WILLCOX, R. R. Some American Ideas on Venereal Disease Control. Brit. M. J. No. 4482, p. 825 (Nov. 30), 1946.

"They Have Come to Stay"—There are papers one reads for profit; others for pleasure—yes, even in the scientific press! If you'll read this one, your pleasure is assured, because it has eloquence, humor, persuasiveness. Incidentally, you may derive a little profit from it. Who knows?

WINSLOW, C.-E. A. The Voluntary Nursing Agency. Pub. Health Nurs. 38, 11:608 (Nov.), 1946.

Also experienced in organizing social service for physically handicapped. Desires position in editorial work, library research, translation, and administrative personnel work. Write Box H-526, Employment Service, A.P.H.A.

Fellowships in Medical Research

Dr. Thomas Parran, Surgeon General of the U. S. Public Health Service, announces approximately 120 one year fellowships in medical research open to men and women who are graduate science students.

The National Cancer Institute, a division of the National Institute of Health, has funds to train approximately 30 physicians in the diagnosis and treatment of cancer. Doctors wishing to specialize in this field may be appointed as trainees and be assigned to authorized institutions.

The National Institute of Health offers research fellowships to graduates of accredited colleges who have majored in biology, chemistry, dentistry, entomology, medicine, physics, and other scientific fields. Senior research fellowships are awarded at a yearly stipend of \$3,000 to those who hold a Ph.D. degree in one of the specified scientific subjects. Junior fellows receive \$2,400 annually and must hold an M.S. degree or have completed the equivalent of such a degree in post-graduate study. Fellowships may be renewed for a second year. Applications for fellowships and traineeships should be sent to the Director, National Institute of Health, Bethesda, Md.

The U. S. Public Health Service also administers fellowships for health personnel from other American republics and the Philippine Islands. Applications for these fellowships should be sent to The Surgeon General, U. S. Public Health Service, Washington 25, D. C.

Fellowships for the Training of Health Educators

The U. S. Public Health Service announces that fellowships leading to a Master's degree in Public Health in the field of health education are again being offered. Candidates must be U. S. citizens between 22 and 40 years of age, must hold a bachelor's degree from a recognized college or university, and must be able to meet the entrance requirements of the accredited school of public health of their choice.

In addition to the degree, courses in the biological sciences, sociology and education may be required. Training in public speaking, journalism, psychology, and work in public health or a related field are considered desirable qualifications.

Tuition, travel expenses for field training and a monthly stipend of \$100 will be

provided out of funds furnished by the National Foundation for Infantile Paralysis. The year's training which begins with the 1947 fall term, consists of 8 or 9 months of academic work and 3 months of supervised field experience.

Veterans are encouraged to apply and will be paid the difference between the allowance under the G.I. Bill of Rights and the monthly stipend of \$100. Employees of local and state health departments are not eligible since Federal grants-in-aid are already available for such training purposes.

Application blanks may be obtained by writing the Surgeon General, United States Public Health Service, Washington 25, D. C., and must be filed prior to March 15, 1947.

Exchange of Public Health Personnel between Hawaii and the Mainland

An opportunity for public health nurses, sanitary and medical officers to work in the Hawaii Health Department is now offered under the new exchange personnel program inaugurated by the Board of Health in the Territory.

As passed by the Hawaii legislature, the enabling act calls for an exchange of personnel for a period not to exceed a year.

Provisions in the act state that each person exchanged by the health department of any state must possess qualifications equal to the qualifications of the person exchanged for him from Hawaii and must hold in the state health department a position which is equivalent to the position held by the person exchanged for him in Hawaii.

Salaries for both exchanging parties will be paid by the home employer. Travel, board, lodging or other such expenses will not be paid by the Territorial Health Department.

Eligible persons employed on the mainland who desire to take advantage of this exchange program are requested to write Dr. Richard K. C. Lee, Assistant Health Executive of the Board of Health, Territory of Hawaii.

Fellowships for Physicians and Engineers

The Surgeon General announces that applications for Fellowships in post-graduate public health training for physicians and engineers, for the school year beginning in the fall of 1947, will be received prior to May 1, 1947. The Fellowships are made possible through a grant given by the National Foundation for Infantile Paralysis.

The Fellowships include nine months of training in an accredited school of public health or an acceptable school of sanitary engineering followed by three months of field training.

Requirements: Under 45 years of age, United States citizenship. Physicians must have completed at least one year's internship. Engineers must have a bachelor's or higher degree in sanitary, civil, or chemical engineering, or another engineering degree with experience in public health or sanitary engineering.

The Fellowships are intended for newcomers to the public health field and are not open to employees of state or local health departments for whom federal grant-in-aid funds are already available to the states. The purpose of the Fellowships is to aid in the recruitment of medical and engineering personnel to help fill hundreds of vacancies existing in state and local health departments throughout the country.

The Fellowships are administered by the Surgeon General's Committee on Training of Public Health Personnel. Applicants may secure further details by writing to The Surgeon General, U. S. Public Health Service, 19th and Constitution Ave., N.W., Washington 25, D. C.

Examinations for Scientists for Appointment to the Regular Corps of the U. S. Public Health Service

Seventy-five vacancies exist in grades of Assistant and Senior Assistant Scientist in the Regular Corps of the U. S. Public Health Service. Written examinations will be held April 14 and 15, oral examinations during the period February 13 to April 9 in thirty cities strategically located throughout the United States.

Commissions are available to scientists trained in any of the following fields: bacteriology, mycology, parasitology, entomology, malacology, biology, chemistry, physiology, physics, statistics (mathematical, demographic, etc.), psychology, and for milk and food specialists.

Requirements: (1) Assistant Scientist:

United States citizenship, 7 years of educational and professional training or experience, certificate or diploma from institution of recognized standing and satisfactory health, as established by physical examination. (2) Senior Assistant Scientist: As for Assistant Scientist, plus four years of additional training or experience.

Remuneration: (1) Assistant Scientist: Annual pay with allowances for dependents, \$3,811. (2) Senior Assistant Scientist: Annual pay with allowances for dependents, \$4,351. For both grades full medical care, hospitalization for appointees and families, including disability retirement, thirty days' annual leave. Periodic promotions. Retirement age: 64.

Application forms and additional information may be obtained from the Surgeon General, U. S. Public Health Service, Washington 25, D. C.

U. S. Public Health Service Announces Examinations for Nurses

Examinations for the appointment of registered nurses to the U. S. Public Health Service will be given during March and April, 1947, in cities throughout the nation, according to an announcement made by Miss Lucile Petry, Chief of the Division of Nursing.

"The Public Health Service offers opportunities for recent graduates as well as experienced nurses," Miss Petry said.

"For the new registered nurse who can qualify here is an opportunity to acquire good initial experience. The Public Health Service offers the experienced nurse a permanent career with the advantages of professionally stimulating work, job security, regular salary increases, and opportunities for advanced study and promotion on the basis of training and ability."

Nurses interested in obtaining further details concerning appointment to the U. S. Public Health Service should write to Miss Lucile Petry, Chief, Division of Nursing, U. S. Public Health Service, Washington 25, D. C. Specific dates for examinations will be announced shortly.

(b) Director of health education; degree in health education or public health nursing required; advantageous if experienced in community health organization, including tuberculosis con-

trol; duties entail clinic service in diagnostic chest clinics and developing health education program; East. (c) Public health nurse to become associated with Division of Cancer Control; considerable traveling throughout state; unusual opportunity. (d) Associate for nursing division, national health agency; administrative ability and experience required; headquarters in New York City. (e) Nurse consultant; duties consist of being responsible principally for education

in tuberculosis and heart disorders of student nurses, in-service programs with school, industrial and bedside nurses, some industrial work; California. (f) Public health nursing supervisor; city department of health; New England; \$3,660. **PH2-1** The Medical Bureau, Burneice Larson, Director, Palmolive Building, Chicago 11.

WANTED—(a) Nutrition consultant qualified to conduct state-wide educational program; \$260-\$300; West. (b) Nutritionist to direct district staff of nutritionists; Master's degree and experience in public health desirable; municipal department of health; \$345; West. **PH2-2** The Medical Bureau, Burneice Larson, Director, Palmolive Building, Chicago 11.

WANTED—(a) Director of health, public school system; enrollment of 20,000; 800 employees; staff of 12 nurses, two dentists, several oral hygienists; preference for physician who has specialized in pediatrics or public health; immediately. (b) Director of division of venereal disease; must be qualified not only in diagnosis and treatment of venereal disease but familiar with direction of general control program; population of county, two million; Middle West; \$7,000 plus traveling expenses. (c) Physician trained and experienced in infant care to direct maternal and child health services, municipal department of health; newly created position unimpeded by politics; woman eligible; \$5,000-\$6,000 with provision for salary advancements to \$9,900; large city in Middle West. (d) Young physician for position of director of health and physical education; public school department of health; staff of 12 nurses, 2 dentists, and approximately 40 physical educational instructors; enrollment of 17,000 students; faculty of 6,000; town of 75,000 located short distances from several large cities including university medical center. (e) Assistant director, student health department, coeducational college; well

equipped 100 bed hospital; town of 18,000 located short distances from several large cities; \$4,500 plus opportunity of private practice; Southwest. (f) Assistant directors for following departments: Adult Hygiene, Administration, Venereal Disease; physicians with Master's degree in public health or minimum three years' public health experience; East. **PH2-3** The Medical Bureau, Burneice Larson, Director, Palmolive Building, Chicago 11.

WANTED—(a) Health educator to take charge of state-wide program, division of one of the national organizations; South; \$4,000 including travel expenses; man preferred. (b) Research statistician experienced in cancer statistics or biological research; unusual opportunity with new institution specializing in cancer research; man preferred; woman eligible. (c) Public relations director, large hospital in the Middle West; preferably someone with minimum ten years' experience in the public relations-financial campaign field; permanent association; \$10,000. (d) Sanitary engineer; state department of health which is being reorganized; salary for recent graduate, \$250; salary for experienced candidate, \$350. (e) Health educator; duties consist of working throughout eastern state with headquarters in capital; degree in public health education required; five years' experience desirable; \$4,000. (f) Sanitary engineer; duties consist of serving in advisory capacity in general overall sanitary and anti-malarial work of large industrial company; preferably someone free to travel. **PH2-4** The Medical Bureau, Burneice Larson, Director, Palmolive Building, Chicago 11.

WANTED—(a) Dentist to join staff of department of health, public school system; Middle Western town of 100,000; full-time, permanent; \$4,500. (b) Dentist preferably qualified in public health dentistry for directorship of dental health in southern state; immediately. **PH2-5** The Medical Bureau, Burneice Larson, Director, Palmolive Building, Chicago 11.

Opportunities Wanted

Health educator; Bachelor of Education degree; graduate courses in sanitation; eight years, supervisor of physical education in public schools; three years, sanitarian; past three years, health educator, municipal department of health; for further details, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Medical editor; B.S. degree; Public Health certificate; several years, public health work; past four years, engaged in medical journalism; for further details, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Nutritionist; B.S. in home economics, M.S. in nutrition; year's fellowship in nutrition during which time she completed vitamin assay of foods; several years on faculty of department of nutrition of university school of home economics; is particularly interested in abstracting nutrition studies or collaborating research findings and nutrition advertising; for further details, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Parasitologist—M.A. (Bacteriology), Ph.D. (Bacteriology and Parasitology); several years science teacher in the public schools; three years assistant in department of pathology, university medical school; six years assistant professor, directing own work in parasitology; for further details, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Public health nurse is available for administrative position in public health; Bachelor of Science in Education with major in Public Health Nursing; past several years, supervisor public health staff, important war project; for further details, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Public Health physician is available; Master's degree in Public Health, Johns Hopkins; twelve years' experience as professor of preventive medicine, public health and industrial medicine, university medical school; for further details, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

NEWS FROM THE FIELD

RESEARCH PLANS ANNOUNCED BY U. S. PUBLIC HEALTH SERVICE

Recent announcements by the U. S. Public Health Service indicate expanded research facilities in several areas, three of which are summarized below.

Coöperative Nuclear Research Program

A nuclear research program will be undertaken at the Clinton Laboratories in Oak Ridge, Tenn. This will be a coöperative venture between a newly created Biological Research Division of the Monsanto Chemical Company, which operates the Clinton Laboratories, and the National Institute of Health. The program will include extensive research into the effect of nuclear radiations upon living cells and to determine the maximum safe exposure for workers in this field. The practical use of atomic energy in industry is dependent upon the solution of problems of maximum safe exposure for workers.

The undertaking will further permit the National Institute to take advantage of new tools being made available at the Clinton Laboratories in its research on such subjects as infectious diseases, nutrition, tropical disease, malignancy, and fundamental studies in biochemistry and physiology.

The program will be in charge jointly of Dr. Alexander Hollaender, Principal Biophysicist of the National Institute, and Dr. Eugene P. Wigner, Research Director of the Clinton Laboratories.

To Study Effectiveness of BCG Vaccine

Following upon reports presented at a recent conference of tuberculosis leaders of the United States, China, and Denmark, the U. S. Public Health Service announced an extension of its tuberculosis research program to include

studies on the effectiveness of BCG vaccine in preventing the disease.

Studies presented at the conference indicate that BCG vaccination confers increased resistance for the limited period covered in these studies, but is not 100 per cent effective. There have been no proved cases of progressive disease resulting from BCG vaccination and it can be used without causing severe local reactions. Although the conference emphasized that BCG vaccine should not yet be made commercially available in the United States, it strongly advocated extensive research to determine the efficiency of the vaccination. It was also recommended that methods be developed to standardize techniques of preparation of a potent and stable vaccine for use in the United States and if possible throughout the world.

Plans proposed for carrying on this research include: establishment of a laboratory to produce BCG vaccine for use in research programs throughout the country; extensive investigations carried on coöperatively by recognized research groups, especially in populations highly exposed to tuberculosis; a controlled study by the Tuberculosis Control Division of the Service in a community of 100,000 or more persons to determine immediate and long-range results; development of standardized techniques of preparation of a potent and stable vaccine.

Memorial Laboratory Dedicated at National Institute of Health

On October 27, 1946, the Memorial Laboratory for the study of infectious diseases was dedicated as the 8th building of the National Institute of Health, Bethesda, Md., according to an an-

nouncement by the Federal Security Agency. The laboratory is a memorial to the 23 members of the U. S. Public Health Service who have died in line of duty; from Dr. Roswell Waldo who died from yellow fever in 1878 to three who were fatally infected in 1944, Dr. Richard G. Henderson and Scientific Aide Philip Leroy Jones with scrub typhus, and bacteriologist Rose H. Parrott with tularemia.

The laboratory will be administered by Dr. Charles Armstrong, Chief of the Division of Infectious Diseases of the Institute. It will be the scene of intensive research on the Rickettsial diseases, undulant fever, tularemia, psittacosis, poliomyelitis and other central nervous system viruses, and the common cold. Many of the unique preventive facilities of the laboratory have been developed as a result of Dr. Armstrong's experiences, who has himself several times been the victim of disease in the course of his research.

LOUISIANA EXPERIMENT IN BIRTH REGISTRATION

A new system of birth registration has been inaugurated in Louisiana. Ten parishes will test the effect of parent participation on the accuracy and completeness of birth registration. Should the experiment result in an improvement in registration, the legal responsibility for registering births will be transferred from the attendant to the parent. Parents will review and sign the child's certificate. The attending physician is to notify the local health unit of the occurrence of a birth within 48 hours after birth. Hospitals are urged to cooperate, as they have in the past, to the extent of preparing the certificate for the mother and making sure she reviews it carefully and signs it before leaving the hospital. The project will test the system for two years as a coöperative experiment between the Division of Public Health Statistics of the State

Department of Health and the U. S. Bureau of the Census. At the end of this period, if considered feasible, legislative revision will be sought to relieve the attending physician of his responsibility in birth registration and to place this responsibility on the parent. The Louisiana State Medical Society has approved the project. Similar innovations are under way in other states and if successful may be adopted on a national scale.

HEALTHFUL LIVING IN FILMS

The McGraw-Hill Book Company (330 West 42nd Street, New York 18) announces a new technique in health education. It will use specially prepared films for supplementing Dr. Harold S. Diehl's *Textbook of Healthful Living*. This popular textbook for college freshmen hygiene courses and adult education groups is by the University of Minnesota's Dean of the Medical Sciences.

McGraw-Hill has started production of a series of seven 16mm sound motion pictures and a like number of coöordinated silent film strips on vital health subjects. These "Text-Films" will be ready for distribution early in 1947. Instructors' Manuals with suggestions for effective integrated use of films and textbooks will also be provided. Subjects of the seven films are: Body Care and Grooming; Personal Health; Care of the Ears, Nose, and Throat; Group and Public Health; Immunization and Vaccination; Sex Education; and Mental Hygiene.

The Manager of the Text-Film Department of McGraw-Hill is Albert J. Rosenberg who has had wide experience in film work and in education at Johns Hopkins University, the University of Baltimore, and the U. S. Office of Education. Technical assistance will be given by Dr. Diehl and three other members of the University of Minnesota faculty; Dr. William A. O'Brien,

Director of Post-Graduate Medical Education; Dr. Ruth Boynton, Director of Students' Health Service; and Dr. Ruth E. Grout, Professor of Public Health and Education.

DIVISION OF SANITARY ENGINEERING IN SOUTH CAROLINA

The Division of Sanitary Engineering in the South Carolina State Board of Health was created on July 1, 1946, making a total of 15 divisions in the department. The Director of the Division is J. H. Stephens, who received his Master's degree in Sanitary Engineering from the Harvard School of Engineering in 1938. He has had twelve years' experience with the South Carolina State Department of Health as well as a year's experience as regional sanitation consultant with the U. S. Public Health Service.

The new division personnel includes, besides Mr. Stephens, three district sanitary engineers supervising the 46 counties of the state, two senior and one junior sanitary engineer, and three principal sanitarians.

DIVISION OF DENTAL HEALTH IN MASSACHUSETTS

On July 1, 1946, the General Court of Massachusetts provided funds for the establishment of a Division of Dental Health in the State Department of Health. This followed upon the combined efforts of the department, the Massachusetts Dental Society, and other agencies. Plans are under way to formulate a comprehensive program of dental care, research, dental health education, and community coöperation. First attention will be concentrated upon the dental health of the child.

DIVISION OF HOSPITAL AND INSTITUTIONAL SERVICES IN INDIANA

Martha O'Malley, M.D., Dr.P.H., has been appointed Director of the newly created Division of Hospital and Insti-

tutional Care in the Indiana State Department of Health. The new division will work closely with the Advisory Hospital and Health Center Planning Committee named by Governor Gates, and will provide consultant service to hospitals.

Dr. O'Malley is a graduate of the Iowa State University Medical College, received the Master's and Doctor's degrees in Public Health in the Harvard School of Public Health, spent six years in the Bureau of Maternal and Child Health of the Connecticut Health Department, and shorter periods as Research Assistant in the Department of Preventive Medicine and Public Health of the Cornell University Medical School, and in the Harvard School of Public Health.

NEW YORK CITY DOGS TO BE VACCINATED

Because of the rapid increase of rabies in the city, the New York City Board of Health will require by law the vaccination of all dogs. During 1946 more than 100 rabid dogs have been picked up in the city and nearly that many persons have been bitten and compelled to take the long course of antirabic inoculations. Three of the Boroughs of the city already were under dog quarantine. It has been decided that no free clinics will be set up by the city to provide this vaccination service.

CHEST X-RAYS FOR UNITED NATIONS SECRETARIAT

In December, 1946, the New York City Health Department provided free chest x-rays for the 2,400 employees of the United Nations at Lake Success, N. Y. The U. S. Public Health Service furnished the equipment and some of the technicians.

Persons in charge of handling and assigning UN personnel indicated that the x-ray survey would be especially useful because a number of the Lake

Success workers would shortly be assigned to work in Europe and other points throughout the world.

SCHOOL OF MEDICINE AT UNIVERSITY OF WASHINGTON

With the current academic year, the School of Medicine of the University of Washington in Seattle opened with 50 students. This is the beginning of a projected Division of Health Sciences of the university which will include a medical, dental, and nursing school, and a medical center including a 400 bed University Teaching Hospital. In 1945, the Washington State Legislature appropriated an initial \$3,750,000 for the project which it is estimated will involve a total investment of from twelve to fifteen million dollars. Department heads have been appointed and teaching staffs have been organized and equipped for the basic medical science divisions.

NON-IMMIGRANT ENTRY AUTHORIZED FOR DOCTORS

The Bureau of Immigration and Naturalization in Washington has authorized the entry into Puerto Rico as non-immigrants of doctors who are not citizens of the United States. The decision applies only to medical personnel who will fill vacancies in the Puerto Rico Department of Health for which qualified Puerto Rican personnel are not available.

NEW YORK PRACTICAL NURSE LAW CHALLENGED

The New York State Board of Regents has recommended the repeal of the law licensing practical nurses. Because of "grave concern" over this prospect, the New York State Nurses Association, through its President, Clare M. Casey, has sent the following telegram to each member of the Board of Regents:

The Board of Directors of the New York State Nurses Association deplores the action

of the Board of Regents in recommending a repeal of the law licensing practical nurses.

We believe that this removes the legal safeguard that assures reliable nursing care to your sick.

Joining with Miss Casey in her organization's protest is Practical Nurses of New York, Inc., the association of practical nurses in the state. There are 64,000 registered professional nurses in New York State and approximately 20,000 licensed practical nurses.

The law licensing practical nurses was passed in 1938. Under this law hospitals have until July 1, 1947, to staff their hospitals with registered professional or licensed practical nurses for all those engaged in nursing care of the sick.

GENERAL MORRISON C. STAYER HONORED

The War Department has announced the award of an Oak-leaf Cluster to the Distinguished Service Medal of Major General Morrison C. Stayer (Ret.), F.A.P.H.A. The citation reads in part:

Charged with safeguarding the health and lives of American troops on the battle fields of Italy and Southern France, and in areas notorious for the prevalence of malignant and exotic diseases, General Stayer as Theater Surgeon, prompted the Medical Services under his control to achieve a record which is generally regarded as a superior standard of efficiency.

General Stayer was Surgeon of the Mediterranean Theater of Operations during the period referred to.

DR. THOMPSON RETIRES

Louis Ryers Thompson, M.D., organizer and former director of the National Institute of Health, concluded 36 years of work with the U. S. Public Health Service on November 1, 1946. A native of Lafayette, Ind., and a graduate of the Louisville Medical College, Dr. Thompson joined the Public Health Service as an Assistant Surgeon in 1910, and since that time has held all ranks in the service, rising to the position of

Assistant Surgeon General in 1930. At the time of his retirement he was Chief of the Bureau of State Services.

Among the most notable of Dr. Thompson's achievements was the organization of the National Institute of Health, of which he was Director from 1937 to 1942. Dr. Thompson has been succeeded by Herman E. Hilleboe, M.D., Chief of the Tuberculosis Control Division since it was organized in 1944. He in turn is succeeded by Senior Surgeon Francis J. Weber, formerly Assistant Chief of the Tuberculosis Control Division.

BURT R. RICKARDS RETIRES

Burt R. Rickards retired as of January 1 as Director of the Division of Health Education of the New York State Department of Health, Albany, having served the department as director of the division for 24 years and having spent nearly thirty years in state service. A special occasion with a dinner December 19 recognized his retirement with a special issue of *New York State News* of which Mr. Rickards has been editor for many years.

After a long career of association with Massachusetts Institute of Technology, the *American Journal of Public Hygiene*, of which he was editor and managing editor, retiring in 1912, with the Massachusetts Association of Boards of Health, with the Ohio State Department of Health and other agencies, Mr. Rickards has announced that he will continue an interest in public health as consultant in the field of health education and public relations.

NEW FOUNDATION FOR THE STUDY OF BLOOD PRESSURE ANNOUNCED

The public press late in December carried an announcement of the establishment of the American Foundation of High Blood Pressure with headquarters in Cleveland, Ohio. The program as announced will include the financing of

medical research to discover the cause and cure of various circulatory disorders. Donald E. Hagaman, Executive of the Greater Cleveland Chapter of the American Red Cross, was to assume the executive secretaryship of the Foundation in mid-February. Alva Bradley is the Chairman and it was announced that funds will be raised at the national level to advance the study of high blood pressure and arteriosclerosis. Funds for the first three years of the program are said already to be in hand.

INTERNATIONAL UNION FOR COMBATING VENEREAL DISEASES

At its first post-war meeting in Paris, November 12 to 14, the Executive Board of the International Union for Combating Venereal Diseases elected William F. Snow, M.D., New York, as its president. Dr. Snow is Chairman of the Board of Directors of the American Social Hygiene Association and of its Committee on International Activities. He spent five weeks in Europe, among other engagements visiting Belgium, Switzerland, and Germany at the request of the Joint Chiefs of Staff. The International Union meeting, attended by 50 persons representing 19 countries of Europe and the Americas, made plans for close coöperation with the new World Health Organization and other United Nations organizations.

Headquarters of the Union are at the Institut Alfred Fournier, 25, Boulevard St. Jacques, Paris XIV. Its Secretary General is André Cavaillon, M.D., of France.

ASSOCIATED MEDICAL CARE PLANS

The Associated Medical Care Plans was recently incorporated under the Illinois laws as a coördinating agency for prepaid medical care plans. It will include all state and local nonprofit medical care plans that comply with the minimum standards for Medical Service approved by the Council on

Medical Service of the American Medical Association. The newly appointed director, Frank E. Smith, Ph.D., will have his headquarters with the American Medical Association, 535 N. Dearborn St., Chicago, Ill. Previous to his appointment, Dr. Smith was for two years Director of Public and Professional Relations in the Los Angeles office of the California Physicians Service.

INSTITUTES IN HOSPITAL ADMINISTRATION

The American Hospital Association announces a series of about 30 institutes in various parts of the country, covering many topics such as medical records, accounting procedures, purchasing, cost analysis, personnel practices, work of nurse anesthetists, dietetics, etc. The calendar of institutes now planned follows:

Feb. 10-14 Purchasing, Drake Hotel, Chicago, Ill.

Mar. 17-21 Medical Record Librarians, Benjamin Franklin Hotel, Philadelphia, Pa. (with the American Association of Medical Record Librarians)

Mar. 24-28 Accounting Executives, United Hospital Fund, New York, N. Y.

Apr. 14-18 Basic Accounting and Business Office Procedures, Chicago, Ill.

May 26-30 Nurse Anesthetists, New Orleans, La. (with American Association of Nurse Anesthetists)

June 9-13 Medical Record Librarians, Denver, Colo. (with American Association of Medical Record Librarians)

Plans are partially completed for two institutes for dietitians in June and for three or four for personnel officers. Others will be announced at later dates. Further information may be secured from the American Hospital Association, 18 East Division Street, Chicago 10, Ill.

VETERINARY PUBLIC HEALTH SECTION OF U. S. PUBLIC HEALTH SERVICE

A Veterinary Public Health Section has been established in the States Relations Division of the U. S. Public Health

Service to conduct demonstration projects on the control of animal diseases communicable to man. This section also will collect epidemiological data pertinent to these diseases. Heading the new program is James H. Steele, D.V.M., M.P.H. Dr. Steele will be responsible for developing the demonstration projects and for consultant services to states in conducting veterinary public health programs. Dr. Steele and his staff will act as consultants to the District Offices of the Public Health Service and will provide special services to state and local health departments at the request of the District Offices.

COÖPERATION IN TRAINING PUBLIC HEALTH NURSES

In Cattaraugus County (N. Y.) the County Health Department and the County Tuberculosis and Health Association are coöperating to train public health nurses. The Health Department will accept four young nurses for a year's training in public health nursing under approved supervision at a salary of \$1,800 plus transportation.

Upon completion of this apprenticeship, the County Tuberculosis Association is prepared to give at least two scholarships for a period of academic study in a curriculum approved by the N.O.P.H.N. The tuition would be paid directly to the university and a monthly allowance of perhaps \$100 made to the student.

At the completion of training students will not be required to return to Cattaraugus County although that is the hope of the coöperating agencies.

Applicants who are high school graduates, have graduated from an approved nurse training school, and are eligible for registration in New York State may apply for this training to: Miss Ida McRoberts, Director of Public Health Nursing, 302 Laurens Street, Olean, N. Y.

1946 NURSING SCHOOL ADMISSIONS BELOW 1936 LEVEL

Nearly 31,000 new students were admitted to 1,271 state accredited schools of nursing in 1946, according to a report recently issued by the Department of Studies of the National League of Nursing Education. This number is about 700 fewer than the number of students registered in 1936 and less than half of those admitted in 1944. The five years between 1936 and 1941 registered an annual increase of from 1,000 to 2,000 new students, until in 1940 there were more than 38,000.

War inspired patriotism and government scholarships were responsible for swelling enrollments during the war years, the number reaching more than 67,000 in 1944. A drop of nearly a fourth in 1945 and another of nearly a half in 1946 indicates a continuing nurse shortage. The report states that nursing and hospital officials, though expecting the inevitable post-war drop, had counted on a quota of 40,000 enrollments in 1946, approximately 10,000 more than were registered. Every state except Mississippi registered a substantial drop in 1946; in 21 states, 1946 admissions were less than half those of 1945.

FACULTY CHANGES AT HARVARD SCHOOL OF PUBLIC HEALTH

Among the recent faculty changes at the Harvard School of Public Health in Boston are the following as listed by the Harvard Public Health *Alumni Bulletin*:

Professor John E. Gordon has returned from Army service as Chief of the Preventive Medicine Service in the European Theater and is now Head of the Department of Epidemiology.

Professor Gordon M. Fair, Head of the Department of Sanitary Engineering, has been made also Dean of the Graduate School of Engineering.

Dr. Harold C. Stuart, Head of the

Department of Maternal and Child Health, has been promoted to the rank of full professor.

Dr. Hugo Muench, formerly Fellowship Advisor with the International Health Division of The Rockefeller Foundation, has been added to the staff as the new Professor and Head of the Department of Biostatistics. He has also been appointed Assistant Dean.

Dr. Hugh R. Leavell, formerly Assistant Director, Division for the Medical Sciences of The Rockefeller Foundation, has been appointed Professor of Public Health Practice and Head of the department.

Dr. John C. Snyder, formerly Lieutenant Colonel in the Medical Corps of the Army and member of the staff of the International Health Division of The Rockefeller Foundation, has been made Professor of Public Health Bacteriology and will have charge of the newly established Department of Public Health Bacteriology.

Other appointments and promotions include:

Dr. Shih L. Chang, to the grade of Assistant Professor of Sanitary Biology; Mrs. Bertha S. Burke and Dr. Samuel B. Kirkwood, as Assistant Professors in the Department of Maternal and Child Health, and Dr. Stuart S. Stevenson, as Associate in that department; Dr. David M. Hegsted, as Assistant Professor of Nutrition; Dr. Marshall Clinton, Jr., as Associate in Industrial Hygiene, and Dr. James L. Whittenberger, as Associate in Physiology.

ULSTER COUNTY (N. Y.) ORGANIZES FULL-TIME COUNTY DEPARTMENT OF HEALTH

The newly appointed Board of Health of Ulster County, New York, with headquarters in Kingston, has organized a staff which began operations on January 1, 1947. Ulster is the third county in New York State to take advantage of the new legislation offering up to 75 per

October 16, 1946. Dr. Garry has been Director of the Tuberculosis Division of the Ohio State Department of Health since 1945. He will be in charge of Tuberculosis Control and Treatment in the Institutions and will also be responsible for organizing the Medical Program of the institutions in the division.

DONALD M. HARRIS, M.D.,* has resigned as Director of Health District 4, with headquarters in Sioux City, Ia., to accept a similar position of the Chippewa County Health Unit at Sault St. Marie, Mich. District 4 includes the counties of Woodbury, Plymouth, Monona, Crawford, and Ida.

ALBERT MILZER, PH.D.,† formerly Research Virologist of the Samuel Deutsch Serum Center, Chicago, has been appointed Director of the Department of Bacteriology, Michael Reese Hospital, Chicago, Ill.

ARTHUR W. NEWITT, M.D.,* Senior Surgeon, U. S. Public Health Service, has been elected to the new office of Tuberculosis Control Officer of Chicago, Ill. He will be on leave from the service only long enough to establish this office. Dr. Newitt has been in the Public Health Service as Tuberculosis Control Consultant since 1931 and in the last 2 years has made control surveys in Chicago, Cook County, and New York City.

CHANGES IN HEALTH PERSONNEL IN OHIO:

ARCHELAUS D. HARVEY, M.D., Lebanon, has been appointed for a 2 year term as Health Commissioner of Warren County.

FORDER F. DEMUTH, M.D., Hicksville, has resigned as Defiance County Health Commissioner.

JOHN A. LOUIS,† Columbus, has been appointed Executive Secretary of the Ohio Tuberculosis and Health Association.

WILLIAM M. SMITH, M.D., M.P.H.,* Bismarck, N. D., has resigned as Acting State Health Officer of North Dakota.

WILLIAM B. WILD, M.D.,† Mansfield, Ohio, has been named Director of the Barry County, Mo., Health Department filling the vacancy that occurred when JOHN K. ALTLAND, M.D.,† resigned to become Director of Local Health Services of the Michigan State Department of Health, Lansing.

Eastern States

REGINALD M. ARCHIBALD, M.D., Associate at the Rockefeller Institute for Medical Research, New York, and special investigator at the hospital, has been appointed Professor of Biochemistry at the Johns Hopkins University School of Hygiene and Public Health, Baltimore, Md., filling the vacancy created by the retirement of ELMER V. MCCOLLUM, Sc.D.† Dr. Archibald will place primary emphasis on biochemistry as related to human nutrition, both in the laboratory and in actual practice.

GEORGE BAEHR, M.D.,* was elected a member of the Board of Directors of the Milbank Memorial Fund in December. The Fund was organized in 1905 to "promote the welfare of mankind" and is currently carrying on a program of research in various fields of public health. Dr. Baehr is President of the New York Academy of Medicine and serves on the directorship of many community and national health agencies, among them the National Health Council, the New York State Public Health Council, and the Health Insurance Plan of Greater New York. He is Chairman of the Lasker Award Committee of the American Public Health Association. He saw service in both World Wars. In the late war, he was first

* Fellow A.P.H.A.

† Member A.P.H.A.

Chief Medical Officer of the Office of Civilian Defense and later Medical Director of the U. S. Public Health Service.

FRANK A. CALDERONE, M.D.,* has been appointed Director of the Headquarters office of the Interim Commission of the World Health Organization, located in the Empire State Building, New York City. During the past ten years Dr. Calderone has been on the staff of the New York City Department of Health, most recently as Deputy Commissioner of Health.

PHILIP W. FENNEY, M.D., of West Haven, Conn., has been appointed Medical Director of the Connecticut State Welfare Department. Dr. Fenney succeeds LEONARD PARENTE, M.D.,† who resigned last month after 4 years with the department, to become Health Officer of Hamden, Conn.

JANET F. NELSON, PH.D., has been appointed Director of Marriage and Family Life Education of the Planned Parenthood Federation of America, New York, N. Y. The service is new and will reach 350 local groups affiliated with the federation to develop services considered essential to the strengthening of the American family. Dr. Nelson has been serving as Consultant on personal and family relationships from the U.S.O. division of the Y.W.C.A.

FRED L. MOORE, M.D., M.P.H.,* who has been Professor of Social and Environmental Medicine at the Long Island College of Medicine, Brooklyn, N. Y., has resigned to accept appointment as County Health Officer in the Barnstable County Health Department, Barnstable, Mass.

THEODORA SHARROCKS, R.N.,† recently joined the staff of the American Journal of Nursing as field representative. A graduate of Presbyterian Hospital and Teachers College in New York, she has been on the supervisory staff

of the Visiting Nurse Service of New York City since 1937.

MORRISON C. STAYER, M.D.,* who retired from the Army with the rank of Major General, has been appointed Director of the Bureau of Tuberculosis Control in the Pennsylvania State Department of Health. Dr. Stayer will succeed DALE C. STAHLER, M.D., who has resigned to enter private practice.

Southern States

JUAN JOSE ALCOCER C., M.D., M.P.H., who recently completed the course at Johns Hopkins School of Hygiene and Public Health in Baltimore, has been appointed Director of State Public Health and Welfare Services in Sonora, Mexico, with offices in Hermosillo.

GEORGE M. DECHERD, JR., M.D., Galveston, Tex., has been appointed Director of the Student Health Service of the University of Texas at the Austin campus. He is relinquishing his positions at the medical branch at Galveston as Director of the Heart Station and as Director of the post-graduate training program but is retaining his title as Professor of Medicine.

C. HOWE ELLER, M.D., DR.P.H.,* formerly Health Officer of the Eastern Health District, Baltimore, Md., has resigned to accept a position as Director of Health of the City of Richmond, Va.

JAMES L. HAMNER, M.D., Mannboro, Va., has been appointed a member of the Virginia State Board of Health, effective July 1, succeeding JOHN B. JONES, M.D., Petersburg, resigned.

CHANGES IN HEALTH PERSONNEL IN KENTUCKY:

EDWARD M. THOMPSON, M.D.. Rus-

* Fellow A.P.H.A.

† Member A.P.H.A.

sellville, has been appointed Acting Director of the Lexington-Fayette County Health Department.

OSCAR V. BROWN, M.D., Island, has been appointed Health Officer of McLean County.

JESSHILL K. LOVE, M.D., Herrods Creek, has been appointed Medical Director of the 11 Cancer Clinics operating in the state.

OKLAHOMA STATE DEPARTMENT OF HEALTH ANNOUNCES CHANGES IN HEALTH OFFICERS:

GEORGE W. WINN, M.D.,† Lawton County Superintendent of Health of Comanche County.

JAMES M. GORDON, M.D., Ardmore, County Superintendent of Health of Carter County.

WILLIAM W. COTTON, M.D., Atoka, County Superintendent of Health of Atoka County.

ALFRED R. SUGG, M.D., Ada, County Superintendent of Health of Pontotoc County.

SAMUEL MARSH, a lawyer of Kansas City, has been named by Governor Donnelly as Director of the Division of Public Health and Welfare. The appointment is subject to confirmation by the Senate. As Director of the Department of Public Health and Welfare, Mr. Marsh is administrative head of three divisions, public health, mental diseases, and welfare, provided by the new Missouri Constitution.

JEAN B. PINNEY,† Editor of the Journal of Social Hygiene, and Director of the American Social Hygiene Association's Washington Liaison Office, during the war years, has returned to the Association's National Headquarters at 1790 Broadway, New York, where she is serving as Secretary of the Committee on International Relations and Activities and Director of the

Liaison Office for International Social Hygiene Agencies and Activities, which is being sponsored by the committee.

SOUTH CAROLINA STATE DEPARTMENT OF HEALTH ANNOUNCES CHANGES IN HEALTH OFFICERS:

CHARLES I. GOODWIN, M.D., Holly Hill, was appointed to succeed the late GROVER C. BOLIN, M.D.,† as Director of the Orangeburg and Calhoun County Health Departments.

CAROLINE H. CALLISON, M.D.,† Chat-ham, has been granted a leave of absence as Director of the Greenwood and McCormick County Health Departments to take a course in Public Health at Columbia University. During her absence MAULDEN J. BOGGS, JR., M.D.,† Health Officer of Abbeville, will be in charge of the Greenwood and McCormick Health Units.

J. H. STEPHENS, M.D., has been appointed Director of the Division of Sanitary Engineering in the South Carolina State Board of Health with offices in Columbia, S. C. Included in the Division are the sections of: water and sewage, milk and shellfish, hotels and restaurants, and meat processing and handling.

CHANGES IN HEALTH PERSONNEL IN TENNESSEE:

JOHN M. WEIR, JR., M.D.,† New York, has been named Health Officer of the Obion-Lake County Health Unit, filling the vacancy that occurred when WILLIAM L. PHILLIPS, M.D.,† resigned last October.

PRICE H. DUFF, M.D.,† formerly of Crassville, has been appointed Health Officer of Rutherford County, Murfreesboro, succeeding JAMES B. BLACK, M.D., who resigned effective July 1.

* Fellow A.P.H.A.

† Member A.P.H.A.

WALTER C. HUMBERT, M.D.,† Erwin, has been appointed Director of Giles and Lincoln Counties.

GEORGE K. HENSHALL, JR., M.D., Chattanooga, has been named Director of the Division of Maternal and Child Health, Chattanooga-Hamilton County Health Department to succeed RUTHERFORD O. INGHAM, M.D.*

CHANGES IN HEALTH PERSONNEL IN VIRGINIA:

J. C. NEALE, JR., M.D., Norfolk, Assistant Director of the Department of Public Health, has been named Director.

PEYTON M. CHICHESTER, M.D., Richmond, Assistant Director, has been chosen Acting Director of the Bureau of Tuberculosis Outpatient service and Crippled children's service.

JACK B. PORTERFIELD, M.D.,* who recently resigned as Health Officer of Richmond, effective November 15, will return to the State Board of Health as an Assistant Director in the Bureau of Local Health Services. He has been succeeded in the Richmond position by CHARLES HOWE ELLER, M.D.,* Baltimore, Md.

JAMES DUDLEY, M.D.,† Health Commissioner of Newport News, has resigned to accept a similar position with the city of Roanoke.

HENRY C. BRADFORD, M.D., Falls Church, has been appointed Health Officer of Fairfax County, with headquarters in Fairfax.

JAMES A. FIELDS, M.D., has been appointed Health Officer of Pittsylvania and Halifax Counties with headquarters in South Boston.

B. RANDOLPH ALLEN, M.D., Director of the Bureau of Communicable

Diseases, Virginia State Department of Health, has resigned to join the Veterans Administration.

WILLIAM A. BROWNE, M.D., Assistant Director, Richmond Department of Health, has resigned.

Western States

CHANGES IN HEALTH PERSONNEL IN WASHINGTON;

HERBERT E. TOMLINSON, M.D., recently released from military service, has been appointed Industrial Consultant for the Industrial and Adult Hygiene Section, State Department of Health.

BURTON A. FOOTE, M.D., of Washington, D. C., has been temporarily appointed Health Officer of Kittitas County, succeeding CONRAD E. ROSDAHL, M.D.,† Spokane, resigned.

CHARLES E. REDDICK, M.D.,† Paducah, Ky., has been named Health Officer of Pierce County, succeeding HAROLD MARKS, M.D., Washington, D. C., who has joined the staff of Pierce County Medical Bureau.

MARY B. CHAMBERLAIN† has been appointed to succeed HELEN HARTLEY, R.N.,† who recently retired as Superintendent of Nurses in the San Joaquin Local Health District, Stockton, Calif., effective January 1:

F. HERBERT COLWELL, DR.P.H.,† has joined the staff of the Public Health Statistics Section of the Department of Health, Smith Tower, Seattle, Wash., and will serve as Public Health Statistical Consultant. Dr. Colwell has had several years of training and experience in public health statistics and will head the Sub-Section of Statistics of this Section.

MAJOR EUGENE M. HOWELL,† recently of the Sanitary Corps, U. S. Army, has been appointed Sanitary Engineer for the San Joaquin Local Health District, Stockton, Calif., effective January 6.

* Fellow A.P.H.A.

† Member A.P.H.A.

ALFRED R. MASTEN, M.D.,† Director, Division of Tuberculosis Control, Colorado State Board of Health, Denver, has been appointed to the Administrative staff of the Oregon State Board of Health, Portland.

FRANK H. RODIN, M.D., has resigned as ophthalmologist to the Bureau of Child Hygiene, San Francisco, Calif., Department of Public Health. Dr. Rodin held this position for 20 years. He has been succeeded by THOMAS G. HALL, M.D.

THERESA WOO, M.D., formerly a captain in the medical corps of the U. S. Army, was recently appointed Pediatrician with the Bureau of Maternal and Child Health of the Board of Health, Hawaii. She succeeds MARTHA W. GROVES, M.D., nee MARTHA C. WAGER, who resigned in June.

HARLIN L. WYNNS, M.D.,* formerly Director of Communicable Diseases of the California State Department of Health, is serving temporarily as Medical Officer of the San Joaquin Local Health District, Stockton, Calif.

Foreign

C. C. P. ANNING, M.D.,† has been appointed Medical Advisor to the Social Services Committee of the Chamber of Mines, Johannesburg, S. Africa. He recently has been admitted to the British Order of CBE for his work in the Italian campaign and he has received the Bronze Star from General Mark Clark of the American Army. He served with the Sixth South African Armored Division in charge of Medical Services.

DAVID RESNICK,* has returned from Paris, France, where he organized the European Public Relations Department of the American Joint Distribution Committee and has resumed his services in public relations and publicity at 1775 Broadway, New York 19, N. Y.

Mexico

RAFAEL PASCASIO JAMBOA, M.D., has been appointed Minister of Public Health and Welfare of the Republic of Mexico. The announcement was made by President Aleman.

Deaths

PORTER JAMES CRAWFORD, M.D.,* Director of the Caribbean region of the International Health Division of the Rockefeller Foundation, died recently at Havana, Cuba, at the age of 51. He joined the Foundation in 1928 and from 1928 to 1934 Dr. Crawford was in Brazil, studying measures for the control of yellow fever. The next 3 years he served in Panama, making studies of the same kind in relation to malaria. He was made Regional Director in 1939.

THOMAS H. MILFORD,† Chief Engineer and Director, Bureau of Sanitation, State Department of Health, Montgomery, Ala., was killed in an automobile accident on November 2, 1946, in Montgomery.

* Fellow A.P.H.A.

† Member A.P.H.A.

The Health Department and Medical Care*

Responsibility of the Health Officer in a Medical Care Program

F. W. JACKSON, M.D.

*Deputy Minister, Department of Health and Public Welfare,
Winnipeg, Manitoba, Canada*

EVER since the first appointment of a full-time health officer, about one hundred years ago, his responsibilities in health administration have increased and broadened until at the moment we find him intimately concerned not only with all aspects of disease prevention and health protection, but with many phases of medical care as well.

Even before this, as far back as 1665, the time of the great plague in England, government officials in their efforts to control the spread of the disease found it imperative to provide treatment facilities. From the so-called pest houses of those days there has evolved a rational provision of treatment hospitals for all communicable disease. Health officers have had written into local, and other government health legislation, the necessary authority to provide the facilities for the treatment of these conditions. Although in the first instance such treatment was not

provided wholly as a function of the state, in the last few years more and more of the population requiring treatment for diphtheria, scarlet fever, and other communicable conditions have been receiving the necessary medical care at the expense of the state. Today in Winnipeg, the capital city of Manitoba, treatment of the major communicable diseases for all persons requiring such service, is provided at the taxpayer's expense.

When official health agencies entered the fields of tuberculosis and venereal disease control it soon became apparent that effectual control of these conditions could be obtained only when treatment of individuals suffering from these diseases was provided; so the health officer was compelled by force of circumstance to make sure that the state had available these necessary facilities to make control effective.

Now almost every health officer has at his disposal ample facilities for the treatment of both tuberculosis and venereal disease. In many, if not most, instances such treatment is considered an integral part of the health depart-

* Presented at a Special Session of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 12, 1946.

ment's function. In nearly all the provinces of Canada these services are provided from tax funds, with no direct charge to the individual.

The care of mental disease has always been the responsibility of government, and in most jurisdictions is now under the control of the health officer. In every province in Canada except one the care of mental disease is a part of the health department's function.

In Manitoba there are operated wholly from tax funds more hospital beds for mental and communicable diseases, including tuberculosis, than all those contained in the voluntary general hospitals.

In the past few years there has been a growing public demand for the further entry of the State into the field of medical care. In one province in Canada, Saskatchewan, cancer diagnosis and treatment has been completely assumed as a health department responsibility, and the service is paid for by the State.

Several years ago there were presented to the federal government at Ottawa many requests that government provide facilities for the treatment of arthritis. The pressure grows year by year. The same applies to the care and treatment of crippled children.

So, whether the health officer likes it or not, as an official of the government he is concerned with and must take part in the provision of medical care, at least in selected fields.

For more than twenty-five years the Provinces of Manitoba and Saskatchewan have had a salaried municipal medical service. In both provinces the control of this type of medical care ultimately became vested in the official provincial health agency. This control not only extends to the protection of the public's interest but also the interests of the medical man concerned in assuring him a reasonable contract. At the present time there are 17 salaried municipal physicians in Manitoba.

In 1942 when the federal government of Canada started to consider the possibilities of health insurance they turned to the federal department of health to gather information and prepare plans for medical care in Canada. The Canadian Medical Association and the official health agencies of the several provinces of Canada, through their organization, the Dominion Council of Health, were constantly consulted during the preparation of the proposed legislation. The Canadian Public Health Association was asked to submit a brief to the Social Security Committee when the proposal was finally being considered. They recommended that any plan of health insurance for Canada should be administered by provincial health departments as part of their regular function. The Canadian Medical Association in their submission opposed this proposal and requested provincial administration by an independent commission with official health representation. When the legislation was finally drafted the decision as to the method of administration was left to the discretion of the provinces. Unfortunately, for the time being, this legislation is in a state of suspended animation due to the breakdown in the Dominion-Provincial Conference negotiations on fiscal need as between the Dominion and provinces.

In the western provinces of Canada where the problem of adequate provision of health services is an urgent one, especially for our rural people, we felt that we could not wait any longer for federal leadership. In both Manitoba and Saskatchewan a start has been made in a medical care program which will ultimately lead to a complete coverage of all our people for both preventive and curative health care.

HEALTH SERVICES ACT

The Department of Health and Public Welfare in Manitoba has noted for

many years, with some considerable alarm, the trend in the distribution of medical facilities, where, despite an increasing rural population, we find a decreasing number of medical personnel willing to locate in our rural areas.

Agriculture is the major industry of our province and its well-being, upon which depends the prosperity of Manitoba, must have four things, in the following order of importance, if we are to make living conditions in our rural areas attractive enough to keep people on the land:

1. More health services
2. Rural electrification
3. Modern educational facilities
4. Better roads

Naturally our provincial government and the public look to their official health agency to plan for better health services.

Our modest Health Plan when it was finally approved by the government, and before its formal presentation to the public, was discussed with organized medicine through the executive committee of the Manitoba Medical Association. All the details of the legislation, the content of services to be provided, the method of payment for these services and their administration, were discussed with and approved by organized medicine before such legislation was formally presented for government consideration. As a result of this policy there was no dissenting voice when the Health Services Act was under consideration by the committee of the legislature, and the bill finally passed the House by a unanimous vote.

A. Preventive services

We believe that the only sound foundation for better health services, from every aspect, is that of prevention. We think that first things come first, so prevention of disease through complete coverage for all our rural areas by full-time local health units is the

first objective of our Plan. In less than two years, 42 per cent of this objective has been obtained, and the province would have been completely covered by 1946 if medical, nursing, and other personnel had been available.

This service is provided by provincially appointed civil-service personnel with local participation in the cost of the service and its administration. We believe that this is necessary in order that we may have a local administrative organization for the other services, such as diagnostic facilities and prepaid medical care.

B. Diagnostic facilities

I think all agree that one of the chief causes of the increasing cost of treating illness is the use of the many new and sometimes expensive diagnostic procedures now considered necessary to practise medicine in an intelligent manner. In our province diagnostic facilities are practically nonexistent in the rural areas, so that rural people must travel many miles to one or the other of three cities where such services are available. This is not only expensive for the patient and his family but has the tendency to centralize medical care in a few places. As a result the chance of a young medical practitioner either practising medicine in a scientific manner or making a reasonable living in a rural district is slim. We believe that if we make adequate diagnostic facilities readily available to all physicians, both these disabilities can be at least partially overcome.

Using the local health unit district as the base and starting point, the diagnostic services will be provided through the local health unit administration and its director. The central government provides the services; the local community will share in the cost and administrative responsibility.

The first diagnostic unit will go into operation in the area where the first

rural health unit was established. The technical personnel has been trained, the equipment secured, and operation of this unit will begin March 1, 1947. Just as quickly as more equipment and personnel are available, this service will be extended, health unit by health unit, until ultimately all rural areas will be covered.

The capital cost of the equipment for the service is assumed by the provincial health department, and all personnel are, and will be, departmental employees. The local community assumes, out of tax funds, one-third of the operating cost. The service will be provided through approved local general hospitals and only on the request of a licensed practising physician.

C. Prepaid medical care

When a community has the two services mentioned, and then only, are they entitled to assistance from the central authority for prepaid medical care. We believe that the treatment of illness is a personal thing between patient and doctor; so the method of prepayment should be left to negotiation between the local community and organized medicine. When this service has been provided by a community, the province will contribute on a per capita basis to the cost of such care.

To standardize the services that may be provided by a salaried physician in a community, there has been written into the law of our province, through the Health Services Act, a standard form of "Municipal Doctor Contract" setting forth the services that the physician shall render, the salary he shall receive, the perquisites in respect to holidays, postgraduate time, etc., to which he shall be entitled. This contract was prepared by an advisory commission under the Health Services Act and has been approved by the Manitoba Medical Association.

We believe this is an important ad-

vance in assuring that a good general practitioner service will be provided for our rural people at a cost that they can afford to assume and will assure the medical man of a decent living and agreeable working conditions. Ultimately, the contract will provide a pension plan and sick leave privileges.

HOSPITAL FACILITIES

Putting a medical man in a rural community to practise is not enough. He must have a workshop, and the doctor's best workshop is and always has been a hospital, so the plan makes provision for this.

Hospitals will be of three kinds: (1) The smallest is a medical nursing unit, for maternity and medical cases. The doctor's office and space for health unit activities will be situated in the same building. We will require about 75 of these units. These will be complementary and contributory to (2) the district hospitals, some 34 in number, varying in size from 25 to 75 or more beds, equipped to do all ordinary major surgery and containing the diagnostic facilities previously mentioned. The district hospitals will be feeders to (3) the area hospitals of which there will be four. Ultimately, each of these will be of a standard capable of doing practically everything required in a medical care program with the exception of thoracic and neurosurgery. These, and some other conditions, in a small province such as ours, should only be treated at the medical center, the teaching center, in Winnipeg.

The capital expenditure required for the erection of hospitals of any type will be the sole responsibility of the community in which the hospital is built. The location of the hospital, its size, the type of construction and the work it shall perform, will be decided by the central authority, the provincial department of health, with the aid of an advisory hospital council. We believe

this control is essential if an orderly development of hospital service is to be provided.

It is interesting to note that material progress is already being made in the reorganization of our hospital facilities. One district has raised by subscription the necessary money to bring their hospital up to standard. Two districts have voted to raise the money by taxation to build new district hospitals. In both instances the vote carried by a large majority.* Three more districts will vote on November 22. Thirteen others either have schemes under consideration or have requested the Minister to prepare a plan for hospital facilities for them. So in 19 of the 26 districts where new construction is required, action has been or is being taken.

SUMMARY

This unpretentious Health Plan in Manitoba makes the health officer, both centrally and locally, the guiding hand in its physical administration, and we believe this is as it should be. Our rural people look to their government for leadership and guidance in this field. They say, quite rightly, that they pay for the up-keep of a health department, which supposedly has personnel especially trained for the protection of the province's health. Medical care is only one phase of that protection, and the public expects us to organize and direct all activities that may be required to provide an adequate all-over health service. This is evident by the fact that the Manitoba Pool Elevator Association, the largest farmer's coöperative organization in our province, is subsidizing the Plan by making a substantial grant to any hospital in rural Manitoba that is remodeled or erected, and that comes within the scope of the Plan, such grant being paid only on the

recommendation of the Department of Health and Public Welfare.

Our government believes that where tax funds are being spent, whether those funds are collected directly or indirectly, the administration spending such money should be held directly responsible to the people through the elected members of the legislature. In Manitoba the administration of the Health Services Act is the responsibility of the Department of Health and Public Welfare.

Ample safeguards both to the public and to the medical profession to prevent so-called bureaucracy are provided in the legislation through the establishment of an Advisory Commission, which adequately represents those providing the service and those who are to receive it. I would like to pay tribute to the work of all members of the Commission, with special mention of the medical members, past and present: Dr. Fred McGuinness, President-elect of The Canadian Medical Association; Dr. Pat McNulty, past-President of The Manitoba Medical Association; Dr. A. Hollenberg, Chairman of the Committee of Medical Economics of the Manitoba Medical Association; and Dr. A. T. Mathers, Dean of the Faculty of Medicine of the University of Manitoba. All have given and are giving generously of their time and special knowledge in order that the Plan may become fully operative as soon as possible and provide better health care for our people.

The Premier of our Province, the Hon. Stuart Garson, in speaking of the Health Plan has said "I do not know of any country whose government has received as whole-hearted coöperation from the medical profession in its attempts to provide better health services than has Manitoba."

I would like to take this opportunity to thank the many organizations in the United States who have helped us in our planning: the American Public Health Association and the Common-

* Four Hospital By-laws were approved by vote of the ratepayers on this date.

wealth Fund for Dr. Carl E. Buck's study in 1941 of "Public Health in Manitoba," the Kellogg Foundation and the American College of Surgeons for assistance and guidance in the survey completed in 1944 of our hospital facilities, and the Rockefeller Foundation for a study just completed on the training facilities required in our province to provide the necessary personnel to implement our Health Plan. The people of Manitoba deeply appreciate this assistance.

In closing I should like to suggest that health officers as employees of government should, with the coöperation of organized medicine, assume the responsibility of assuring that the maximum effort is put forth so that everyone; no matter where he may live or what his economic status may be, has without unnecessary delay, everything medical science has to offer for the promotion of health, the prevention of disease, and the care of the sick.

The Year 1946 in Public Health

In the 1946 annual reprint of the U. S. Public Health Service recently issued, Surgeon General Thomas Parran hailed three moves of the year as great public health advances. They are:

a. The Hospital Survey and Construction Act which established a national policy whereby hospitals and health centers are to be planned, located, and operated in relation to the overall health needs of the people;

b. The National Mental Health Act which provides for research and other facilities for dealing with the mental disorders that affect, to some degree, about 8,000,000 Americans

and fill more than half the country's existing hospital beds;

c. The constitution of the new World Health Organization setting forth a new philosophy of international health relations that it is in the interest of the more advanced nations in health matter to assist less fortunate nations.

He pointed out two frontiers of public health not yet conquered—the area of chronic diseases, particularly those of old age, and the extension of necessary health services to all citizens, regardless of geographic and economic inequalities.

The Health Department and Medical Care*

Maryland Medical Care Program

DEAN W. ROBERTS, M.D.

*Chief, Bureau of Medical Services, Maryland State Department of Health,
Baltimore, Md.*

THE Maryland Medical Care Program is the product of a careful study of community medical care needs conducted by the State Planning Commission over a period of four years. The study was originally suggested in 1939 by the State Medical Society in an open letter to the Planning Commission which pointed out many of the existing deficiencies in provisions for medical services. A field survey of each county was carried out in order to evaluate the particular needs of individual counties.

On completion of the study in 1944 the Planning Commission had reached the conclusion that there was no agency in the state, either official or nonofficial, whose particular responsibility it was to see to it that the poor received adequate medical care. The remedial recommendations of the commission were endorsed by the state medical society, and in 1945 a law was passed charging the State Department of Health with the responsibility of administering a program providing medical hospital, nursing, and dental care for the indigent and medically indigent of the state. The term "indigent" has been defined for the purposes of this program as those persons who are recipients of public assistance from the Department of Public Welfare. A per-

son is "medically indigent" when he is unable through his own resources to provide himself and his dependents with proper medical, dental, nursing, and hospital care without depriving himself or his dependents of necessary food, shelter, clothing, and similar necessities of life. Other new laws provided for the licensing of all hospitals and nursing homes, and for the construction of three chronic disease hospitals with a total of 1,300 beds, to be administered by the State Health Department. The 1945 State Legislature also passed a law enabling hospital insurance plans, such as Blue Cross, to expand their voluntary insurance program to include coverage of the services of private physicians as well as the services of hospitals. The Legislature has made provision, therefore, for adequate medical care through taxation for those with little or no income, and through voluntary insurance for the middle income group who can meet the cost of medical care by the payment of regular insurance premiums.

COÖPERATION OF MEDICAL PROFESSION

The endorsement of the program for the indigent and medically indigent by the medical profession represents an important landmark in Maryland. It represents the finding of a common ground of agreement as regards medical care between the state government and the medical profession. The responsi-

* Presented at a Special Session of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 12, 1946.

bility of government to provide care for the medically indigent is clearly recognized, and a framework is established for a developing partnership between government and the medical profession, with the goal of bringing high quality care to a group of the population who in the past have received grossly inadequate medical care. The importance of this common ground of agreement between government and the medical profession cannot be overemphasized.

The discussion of public medical care has frequently been so inflamed by proposals totally unacceptable to professional groups that many have gained the impression that coöperation toward a common goal is impossible. Professional groups resist sweeping proposals placing government in a dominant position in medicine because they are afraid of what it will do to them as individuals and as professional groups. This seeming impasse can be resolved if agreement can be achieved on limited programs and if government can administer these limited programs in such a way as to provide improved services through administrative methods acceptable to physicians, dentists, and hospitals. The confidence of professional groups will be gained, not by angry debate, but by coöperative exploration of areas of agreement.

MEDICAL CARE FOR NEEDY IN HEALTH DEPARTMENT

Responsibility for medical care for the needy has fallen on the shoulders of welfare agencies in a majority of the states more by default than by plan. Those in charge of public assistance programs have been sensitive to the medical needs of their clients and have developed a wide variety of programs in an attempt to meet these needs. The Maryland Planning Commission recommended that the administrative agency for this Medical Care Program be the Health Department. This decision was

based on their conviction that medical care was a logical and appropriate expansion of health department activities. Physicians in general prefer to deal with medical agencies and in Maryland they indicated a clear preference to have the program administered by the Health Department rather than by the Welfare Department. The long experience of the Health Department in administration of preventive medical programs of a categorical nature such as tuberculosis, venereal disease, crippled children, and maternal and child care, provides a background on which a general medical care program with emphasis on prevention can be built.

There is no inconsistency between the traditional preventive activities of health departments and the administration of medical care programs. Early diagnosis and treatment are in themselves preventive measures and are appropriate responsibilities of a health agency. Public health recognized long ago that the prevention of tuberculosis could not be divorced from treatment; that the prevention of maternal deaths lay in the modern treatment of the pregnant woman. It is equally true that the prevention of deafness lies in the proper treatments of otitis media; that the prevention of pneumonia is partly through treatment of common upper respiratory infections. Cancer deaths are prevented through detection and treatment of early cancer and pre-cancerous lesions. Positive dental health involves treatment of dental caries before the tooth is destroyed. Any dividing line drawn between preventive medicine and curative medicine is, therefore, highly artificial.

IMPLEMENTATION OF MEDICAL CARE PROGRAM

The implementation of the medical care law began with the organization of the State Council on Medical Care, an advisory group representative of the

official medical, dental, pharmaceutical, nursing, and hospital associations, as well as the two Maryland medical schools, and official state health and welfare agencies. This group has met monthly and has guided the State Board of Health in the development of every phase of the program. One of the early decisions was that the program be decentralized and that local administrative responsibility be placed in the county health departments in order that diagnostic and curative services might be more fully integrated with preventive services. County advisory committees, composed of physicians, dentists, pharmacists, representatives of health and welfare agencies, the county commissioners and other lay groups, were established in each county to assist the health officer in organizing the program and carrying it out. Counties were given a wide latitude in determining services to be offered in order that the program might be tailored to meet the most pressing needs of each community. All counties provide home and office care by physicians, drugs, and care of acute dental conditions. County programs vary considerably, however, in the degree to which services such as, surgery, obstetrics, consultations, elective dentistry, nursing care, and diagnostic laboratory services are provided. These differences reflect variations in need from county to county and limitations of program due to budget.

Experience is showing that a simple means test for the medically indigent can be applied by the health department staff without embarrassment of the patient and without developing special investigative machinery. Eligible persons, whether indigent or medically indigent are provided with wallet size identification cards which they are instructed to present to the physician of their choice if they become ill. The physician renders the needed services and at the end of the month submits a

brief medical report to the county health department. After approval by the county health officer, data on this report are transmitted to punched cards, and a payroll and other statistical data are run off mechanically. Payment is issued on a fee-for-service basis following a uniform fee schedule adopted after consultation with county advisory committees. Similar procedures are followed in the provision of dental services and drugs.

SERVICES RENDERED

The volume of services rendered has grown rapidly, and currently the program provides services to approximately 3,300 persons per month, of which 83 per cent are indigent, that is, public assistance clients, and 17 per cent medically indigent. Counties have varied widely in the emphasis placed on the medically indigent phase of the program, and in some counties as high as 60 per cent of the patients are in this group. The monthly cost of services is about \$25,000, of which 80 per cent is for physician services, 13 per cent for drugs, and 7 per cent for dental care. In reviewing these figures it must be borne in mind that the program is serving only the counties of Maryland and that Baltimore City is not covered. The counties have a total population of about 1,000,000 and a public assistance load of approximately 15,000 individuals. The implementation of the program has been facilitated by the fine spirit of coöperation of professional groups. Approximately 75 per cent of the physicians, 70 per cent of the dentists, and 90 per cent of the pharmacies are rendering services through the program.

The majority of the patients are in the older age groups and most of them have chronic illnesses requiring care over a long period of time. Facilities for the care of this group will be greatly strengthened on completion of the three

chronic disease hospitals. The raising of standards of nursing homes through administration of the licensing law will also be an important factor in the provision of better care for the chronically ill.

SERVICES PROJECTED

The primary objective of the program is to bring adequate medical, dental, and nursing care to the poor. Inability to pay must not prevent people from getting good medical care early in the course of disease. It was not expected that this goal would be fully achieved in the first year. The program has many deficiencies which must be overcome by carefully planned extensions to meet the most pressing needs. Emphasis must be placed on early diagnosis and treatment. Early diagnosis frequently depends on the diagnostic facilities available to the physician. It will be important for the health department to provide essential diagnostic facilities in communities where they are not otherwise available. The importance of staffing and equipping the branch laboratories of the health department for the performance of clinical laboratory tests, such as hematology, blood chemistry, urinalysis, etc., cannot be overestimated. Many counties have requested consultation clinics. Shortage of personnel has made this impractical until now, but it should soon be possible to bring consultation services in the major medical specialties to every county, either through visiting consultants or through qualified local consultants.

Although the dental phase of the program has made progress, it still meets only a small fraction of total dental needs of the poor. Even though money were no problem, there are not enough dentists to do the work needed. The program is caring for a predominantly elderly group whose teeth have been neglected for many years. It is im-

practical to provide the fillings, extractions, and dentures required to bring back good dental health to this group. Instead, emphasis must be placed on relatively complete dental care for children and young adults, to prevent their teeth from becoming hopelessly decayed.

The medical care law provides for bedside nursing for eligible persons. Many chronically ill persons now admitted to hospitals or nursing homes could be satisfactorily cared for at home with a reasonable amount of help and guidance from properly trained visiting nurses. Due largely to the acute shortage of personnel, the volume of nursing care provided has remained quite small. This phase of the program is being developed through the public health nursing staff of the department. Nurses' bags are being provided with the equipment necessary for bedside nursing and an in-service training program will bring the public health nurse up to date on bedside nursing techniques. A demonstration has been started in one county in which we hope to develop in detail, sound working policies for a rural community nursing service. Full development of such a program in all counties will require the doubling or tripling of present nursing personnel and will hinge considerably on funds made available for this purpose.

Due largely to inadequate budget, the program has provided for only a small fraction of the medically indigent who need help in obtaining adequate medical care. The need of this group is fully as great as that of the public assistance clients. With the return of normal unemployment levels they will present a problem which must be met.

SUMMARY

For the past sixteen months the state and county health departments in

Maryland have been responsible not only for preventive medicine but for diagnostic and curative medicine for the individual patient. This new responsibility has brought with it adventures on a new frontier which offers public health its greatest opportunity for constructive leadership. Although many unmet needs remain, the Maryland program can point to certain achievements. For the first time the state government has made it public policy to provide medical care to the needy. The health department was honored by being chosen to implement this policy. It has been possible for the health department to sit down with interested professional and lay groups and, through democratic procedures, plan a program upon which all could agree. In many communities

the program has for the first time brought social, professional, and lay groups together in a constructive effort to coordinate their many activities bearing on the field of health.

The fear of some that responsibility in the field of medical care would somehow interfere with the traditional preventive work of the health department has not materialized. There are numerous ways in which the preventive and curative phases of the program can be integrated so as to be mutually supportive. Finally, the activities of the health department in this field has focused attention of the public on health work as never before. Relationships with physicians and other professional groups have been strengthened at both state and county levels.

Federal Civil Service Examinations for Statisticians

The U. S. Civil Service Commission announces an examination for probational appointment to high-grade statistician positions in Washington, D. C., and vicinity at annual salaries ranging from \$5,905 to \$9,975. Applicants will be rated on their experience and relevant training without written examination. Applicants must have had progressively responsible professional

experience in statistical research. At present applications will be considered until further notice.

Applicants who wish early appointment, however, should request application forms immediately from first- or second-class post offices, the Commission's regional offices, or direct from the Civil Service Commission, Washington 25, D. C.

The Health Department and Medical Care*

Group Practice in Preventive Medicine

DEAN A. CLARK, M.D.

Medical Director, Health Insurance Plan of Greater New York, New York, N. Y.

WHEN we speak of "preventive medicine" we are very apt to think primarily of the brilliant sweep of modern public health science across the country, reducing or even eliminating water-borne and milk-borne infections, venereal diseases, malaria, yellow fever, or typhus. Or perhaps we have in mind the prevention of the ravages of diphtheria through mass immunization. But usually we put as distinctly secondary the innumerable preventive measures for the individual that must so largely be carried out by the practising physician. Yet today it is these individual preventive measures which constitute the main hope for the prevention of disease and disability.

PREVENTIVE AND CURATIVE MEDICINE

As a matter of fact, if we are to understand the potential scope of prevention by modern techniques, we must agree that "Any procedure which serves to ward off disease or maintain health is to be considered preventive medicine." This definition, phrased by William Davis† is broad indeed but none too broad to make clear the real issues we are facing. Davis continues, "Such preventive procedures defy classification into rigid groups, for they range from the impersonal measures of environmental sanitation to curative

medicine for the individual. Is the hospitalization and treatment of a woman with typhoid fever to be called curative medicine for her or preventive medicine for the community? Should the early treatment of syphilis be classified under contagious diseases or under the prevention of mental disease? If a man has a job where he eats irregularly, is tense, and has indigestion, and he sees his doctor and as a result gains insight into his anxiety, is placed at a different job in his industry, goes on a better diet and gets well, is this a triumph for gastroenterology? or industrial hygiene? or nutrition? or psychosomatic medicine? And is it curative of anxiety or preventive of a stomach ulcer?"

The point is, obviously, that preventive and curative medicine are no longer separable (if indeed they ever were); both must be included in anything we would wish to recognize as complete medical care. The health officer and the practitioner are both involved in preventive medicine today—in fact, the larger share now belongs to the practitioner, although many in both the public health and the medical professions fail to recognize it as yet.

Take, for example, the prevention of communicable disease, traditionally the realm of the health department. In the case of measles, it is the practitioner who must first take steps to administer gamma globulin if the new-born infant is to be spared this serious disease, caught from his older brother or sister. Even where the technique of preven-

* Presented at a Special Session of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 12, 1946.

† Davis, William A., M.D., Assistant Professor of Preventive Medicine, New York University College of Medicine. Unpublished paper.

tion is largely through mass measures, the attending physician must be relied upon to recognize the disease, properly isolate and treat his patient, and report the case, say, of diphtheria, malaria, dysentery, or indeed venereal disease, tuberculosis, and smallpox.

But, in the fullest sense, prevention is not confined to stopping the *communication* of such diseases; it is equally concerned with the prevention of their complications or sequelae. It is the practitioner who is responsible for the prompt and efficient treatment of pneumonia or scarlet fever or meningitis if his patient is not to have life-long crippling effects from them.

The physician's rôle in prevention can be even more easily seen in diseases which are not communicable. Only the expert diagnosis and intelligent treatment of the physician can prevent the otherwise almost certain destructiveness of cancer, diabetes, hyperthyroidism, glaucoma, the allergies, and emotional disorders. More general recognition has already been given to the preventive functions of practitioners in pregnancy and in infancy.

The techniques used by the physician in his preventive activities run the whole gamut of medical science, from a careful history and physical examination to the most complex laboratory, x-ray, or instrumental procedures, from thyroid surgery to health education. Indeed, every type of skill and every technical device known to medicine has its preventive as well as its diagnostic or curative rôle to play.

The preventive medicine of today, then, is extricably bound up with the quality and distribution of medical care. It is safe to say that at least three-fourths of the preventive work made possible by present-day medical science must be carried by the practicing physician. It follows, obviously enough, that any health officer or other public health worker who desires ma-

terially to increase the effectiveness of preventive medicine today must devote a major portion of his effort to improvement of the organization of medical, dental, and nursing services, and to their adequate application for the benefit of the individuals of the community.

GROUP MEDICAL PRACTICE

The very breadth of scope of the preventive measures we can now apply with scientific exactitude indicates that no single physician, however brilliant, can hope to furnish them all. No one individual can possibly acquire all the skills that are required for surgery, psychiatry, ophthalmology, and internal medicine.

Health departments learned this lesson long ago. A health officer is hardly expected to be public health nurse, sanitary engineer, statistician, venereal disease and tuberculosis control officer, and maternal and child health specialist—all at once. Public health administration has recognized the importance of team work by a group of especially trained persons. In medical practice, on the other hand, it has taken longer to accept this notion.

But besides the team of special skills, there is also the question of equipment. No single physician could hope to own and use all the apparatus or to retain all the technical assistants these skills must have to be effective. Even if he were a Croesus and could afford all these, sheer lack of time would make it impossible for him to use them more than a fraction of the time—for the most part they would be idle and wasted.

Complete preventive medicine, then, requires all the elements now recognized as required for medical care. This means that physicians of different general and special skills need to pool these skills for their patients' benefit, using in common the necessary equip-

ment and assisting personnel. A technique for accomplishing this, group medical practice, originated in the United States half a century ago at such famous centers as the Mayo Clinic, and has gained wide acceptance in recent years. In group practice, the various techniques essential for examining, diagnosing, and treating individuals are brought together in a team, making easily accessible the refinements needed if prevention is really to be practised.

Furthermore, group practice, through the pooling of income and expenditures, makes possible great economies in time, skill, and equipment. Younger physicians entering a group can immediately be fully occupied in accordance with their abilities, under the supervision of the senior members of the group, instead of spending one-third to one-half of their time waiting, in isolation, for patients to come to them. It means that the physician of the group can call upon consultants and laboratory services as frequently as he needs them with great professional advantage to himself and his patients, and without economic loss to him—because the group as a whole gains from every service performed by any of its members. It means, moreover, that the cost of expensive equipment and of highly trained technical personnel is shared by the whole group rather than being borne by a single physician. Finally, the group can make use of its equipment and personnel to the fullest advantage, keeping them occupied at capacity levels.

Through group practice, therefore, the potentialities of modern medicine for prevention can best be fully realized. It should be made clear that group practice should and can be so organized that the personal relationship between patient and physician is maintained and, indeed, enhanced. The patient of a group is actually under the general care and supervision of one

physician who becomes that patient's personal doctor in as full a sense as could any individual practitioner. But this family physician, new-style, has the specialists and laboratories of the group to aid him, while he retains general supervision of the case. Thus the patient's personal physician in a group is the key man of a medical team combining the intimate knowledge and appreciation of the family doctor with the most highly developed scientific skills of his colleagues—skills which are beyond the reach of the individual family physician, old-style. This medical team makes possible the best preventive medicine because the family physician's knowledge of the personal, social, occupational, emotional, as well as physiological circumstances of his patient can thus be utilized in coördination with the special techniques of other members of the team, including those of the nurse, the social worker, the dietician, and the health educator, as well as the physician, to study and promote the health and well-being of the patient, to prevent the spread of illness, to diagnose and treat it early and to mitigate its disabling effects.

PREPAYMENT FOR MEDICAL CARE

But no story of group practice in preventive medicine is complete unless we consider how the preventive benefits of group practice can be made accessible to the patient. Although group practice is economical, the costs of complete modern medical care remain high in relation to the average pocketbook. Much of the potential value of medical science for preventive medicine is lost today because under the fee-for-service system of payment, people do not go to the physician—or the medical group—for regular examination, and for early diagnosis and treatment. Illness, and, with fee-for-service payment, the costs of illness, are unpredictable for the in-

dividual and, consequently, budgeting for health becomes impossible. In any one year, the unevenness with which illness strikes results, under the fee-for-service system, in almost half of the nation's total medical bill being borne by about 10 per cent of the people—and this, of course the 10 per cent who happen to be ill that year and can therefore least well afford to pay.

If medicine is really to serve people for preventive purposes, it must be made accessible to them through methods of payment which will encourage early and full use of comprehensive service. This is only possible through prepayment, or insurance, for medical service. Insurance for the costs of surgery and obstetrics or other limited services is helpful in meeting the costs of catastrophic illness, but it is almost useless as a preventive measure.

The real possibilities of preventive medicine can be achieved only through group medical practice combined with insurance for comprehensive service. This combination has proved to be successful in numerous instances in industrial organizations like the Northern Pacific Railroad, whose plan was founded in 1882 and is still operating successfully, in private groups like the Trinity Hospital of Little Rock, Ark.; and in coöperative plans like the Farmers Union Hospital in Elk City, Okla. These and many other similar examples have shown that insurance for comprehensive medical service can be professionally and economically successful when physicians are organized in groups and are paid according to their time and skill, rather than by fees-for-service. If the possibilities for prevention are to be fully realized, of course, "comprehensive service" must include not only physicians' and hospital services, but dental and nursing care, drugs, and appliances as well.

· RÔLE OF PUBLIC HEALTH PROFESSION

Preventive medicine, viewed in this light, is a large order, but it is one which people generally, aware of the scientific achievements of medicine, have begun to recognize as what they want to have and to pay for, as their means permit, just as they want other more general measures which conduce toward positive health, like housing, recreation, nutrition, education, and a decent standard of living. The public health profession, dedicated to the prevention of disease and the promotion of health, is therefore obligated, together with the medical, dental, nursing, and other health professions, to take the initiative in meeting this demand, to assist the community to obtain preventive medicine in its fullest sense, for all of its people. Many difficulties are to be overcome, as we have found in our attempt to solve these problems in the Health Insurance Plan of Greater New York, but they are not insurmountable. Complete preventive medicine can become a reality for all. This will require, however, not merely the best efforts of the health professions, but the combined energies of all sections of the community: of business, labor, agriculture, government, and the professions. For preventive medicine and achievement of positive health are problems not simply for sanitary engineers and doctors and nurses and dentists. They are the natural concern of every person. Everyone's health is what is at stake, after all. If preventive medicine means anything it means not only the prevention of the communication of disease (and even here the physician must take the first steps toward prevention), but also the prevention of the sequelae, the prevention of unnecessary handicaps and disability, and the prevention of emotional disturbances and their results. So it is fair to say that this kind of preventive medicine is a challenge to us all. Upon our success,

then, in leading the community to organize modern medical skills into teams for the people's benefit, and upon our ability and willingness to assist in making these skills accessible to all through prepayment for comprehensive service will depend the prospects of better health for the American people.

Progress in World-Wide Coöperation in Public Health

The Interim Commission of the World Health Organization recently reported gains made in the past year. Seven major steps relating to world health have been taken:

1. Adoption by the International Health Conference, convened in New York, of the World Health Organization Constitution.
2. Establishment of an interim commission for giving emergency public health aid to certain war torn countries.
3. Transfer of the health functions of the

League of Nations to the World Health Organization's Interim Commission.

4. Transfer of the epidemiological information service of UNRRA to the Interim Commission.

5. Transfer from UNRRA of emergency field assistance in certain areas.

6. Authorization of six technical committees dealing with yellow fever, malaria, narcotics and other subjects of primary public health importance.

7. Institution of a fellowship program for study in the United States, Canada, and other countries of specialists in public health, sanitary engineering and medicine.

The Health Department and Medical Care*

Certain Trends

JOHN B. GRANT, M.D., F.A.P.H.A.

The International Health Division, Rockefeller Foundation, New York, N. Y.

IN his recent *Medical Education and the Changing Order*,¹ Allen states: "Medicine is coming of age as a social science in the service of society." The three previous papers in this session imply that health departments which largely have stabilized administration for the hygiene of the environment, the control of communicable disease, the organization of medical and nursing service for the early diagnosis and preventive treatment of disease in the individual, and to a lesser extent the education of the individual in principles of personal hygiene and of preventive medicine, are now evolving toward their ultimate responsibility. This is the promotion of positive health for each individual to achieve and maintain optimum health of mind and body. As such, public health is indeed a field of social service. One of the chief factors in reaching this end will be the extent to which health workers see their responsibility to establish the *organization* required to *distribute* good medical care.

ADMINISTRATIVE PRINCIPLES

The eventual effectiveness of public health progress is determined by the soundness of the principles upon which its administration is based. Since the first World War principles have been

enunciated in many countries, including the United States. The following three derived from English experience appear to be the most significant.

1. The Magna Carta of administrative principles was enunciated by the British Ministry of Reconstruction in 1919 and led to the establishment of the Ministry of Health:

The first principle of good administration requires that when a special function is to be undertaken, it shall be undertaken by one governing body for the whole community needing the service, and not for different sections of the community by several governing bodies.

2. The Interim Report, on the Future Provision of Medical and Allied Services² said:

Preventive and curative medicine cannot be separated on any sound principle, and in any scheme of medical services must be brought together in close coördination. They must likewise be both brought within the sphere of the general practitioner, whose duties should embrace the work of communal as well as individual medicine.

3. More recently the Interdepartmental Committee on Medical Schools³ stated:

The first step in the experimentation and demonstration of progress in new forms of medical service is its establishment by the teaching hospitals.

Trends particularly in Scandinavia and the British Commonwealth are toward fulfillment of these three principles under the guidance of public health administration.

* Presented at a Special Session of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 12, 1946.

The United States is the only industrialized country in which the above principles continue to be largely ignored. The multiplicity of authorities at both federal and state levels which have health and medical responsibilities is so well known as to require no elaboration. Public health and curative medicine are almost always under separate administrations, and as yet the Association of American Medical Colleges has given no indication of any interest in the responsibility of the teaching center for progress in establishing new forms of medical service.

The achievement of health departments in controlling sanitation of the environment and the incidence of communicable diseases with the consequent improvement in mortality rates has already resulted in the well known marked shifts in the age distribution of population and has disclosed the three major lags in medical care; namely, rehabilitation, chronic illness, and mental care. Each of these, to a greater or lesser extent, is the concern of the health authorities, but hitherto this has been fragmentary and inefficient. At both federal and state levels, the care of the chronic sick is limited to recipients of public assistance and is the administrative concern of welfare rather than health authorities. Rehabilitation at the federal level comes under the Office of Vocational Rehabilitation, and at the state level it is the concern of medical authorities, but is divided between education and welfare. Mental care at the federal level is a public health responsibility, but at the state level responsibility is distributed between welfare and special mental administrations. Further examples could be enumerated of violations of the first fundamental principle quoted above that good health administration requires that all health functions in the community shall be undertaken by one governing body and not for different

sections of the community by several governing bodies.

This chaotic situation has been partly, although not wholly, due to the belief that the addition to limited public health activities of hospital administration which has larger budgets would swamp "public health" which would be the first to suffer in any retrenchment. There were undoubtedly some grounds for this view in the past, but these will be found increasingly untenable in the future. Once the essential environmental and infectious disease services have been completed, health will not further progress satisfactorily until preventive and curative medicine are brought under a single coördinated administration which includes the general practitioner (along the lines to be described for Schoharie County). This is a shared responsibility: education on the one hand should assure the competency of the medical personnel, and public health administration on the other hand should assure the organization for efficient distribution.

The previous papers indicate that initial steps to improve the present situation are being considered. The reasons for this trend become obvious when one envisages forthcoming medical practice with the present emphasis on diagnosis and therapy overshadowed by emphasis on rehabilitation and on positive health. The British Medical Association and the Canadian Public Health Association have declared that the family rather than the individual should hereafter be the unit of the general practitioner. The recently enacted English National Health Services Act, 1946, emphasizes preventive medicine as logically an integral part of curative medicine by transferring from the health authorities to the general practitioner responsibility for the professional aspects of personal health services, such as maternity and child health. In the

United States these must necessarily continue the responsibility of health authorities in the absence of prepayment for medical services, which in England have now been extended to the population as a whole. The Act furthermore accepts the recommendation of the Goodenough Report that medical schools and their hospitals become partners in the national health service. Medical education in England is consequently in the process of thorough reorganization in acknowledgment of the thesis put forward in the Goodenough Report that "Properly planned and carefully conducted medical education is the essential foundation of a comprehensive health service."

The unit of organization in this projected reorganization of the British national system of undergraduate medical education is a medical teaching center consisting of a university medical school, a group of teaching hospitals (parent-associated), and such clinics of the health service of the district as are needed for teaching purposes. In deciding the importance to be attached to various subjects and the type of instruction, the educational reforms are directed toward the needs of the future general practitioner. Special importance is laid on the prevention of disease and an appreciation of the part played by social environment in health and sickness, diagnosis of acute medical and surgical conditions, child health and infectious diseases, the recognition of emergency and of malignant diseases, the milder forms of mental and nervous disturbance, minor ailments, chronic sickness, and rehabilitation. It is because the preventive and social aspects of such training can be given only in the community that health centers are being provided as an integral part of the system of undergraduate medical education. In brief, the principle underlying the recent U. S. Public Health Service *Bulletin* 292 on "Health Service

Areas"⁴ has now become legislation in Great Britain. This increasing integration of the medical school with the health needs and medical care activities of its community is the most significant trend today toward raising the level of health.

Reference should be made here to three experimental demonstrations in the United States: that of the Bingham Associates in Boston, the Council of Rochester (N. Y.) Regional Hospitals, and the Michigan Community Health Project. These projects are designed to improve the technological competency of medical personnel and the adequacy of their diagnostic tools. The recently concluded report of the Commission on Hospital Care of the American Hospital Association recommends removing the present sharp separation of preventive and curative medicine to the extent, at least, that health departments should form joint councils with hospitals to effect coördinated programs. The Commission also recommends that health centers should be part of, or adjacent to, strategically located hospitals. It is anticipated that close physical relationship between hospital and health agencies, including volunteer agencies, should help to integrate activities, particularly those of related programs.

NEED FOR HEALTH-MINDED LEADERSHIP

These trends very distinctly indicate two things: First, the attainment of a high standard of physical and mental health is largely the eventual responsibility of medical practitioners. Second, public health, having gone so far in the effective control of preventable diseases, should next tackle the problem of making generally available the skilled medical services necessary to maintain and promote mental and physical health. Unless the public health profession realizes this increasing responsibility, it will lose the opportunity of preserving and maintaining

the primacy of preventive medicine. To maintain balance in organization for the distribution of medical care and to assure its promotion of positive mental and physical health, it is necessary to have at the top health-minded rather than disease-minded persons. Naturally, clinicians must have full responsibility in clinical fields, and hospital administrators have full responsibility for hospital administration; but in the whole scheme of things, it is the health officer rather than the hospital officer who should plan, and who, at the top, should have the last word in advising on allocation of resources. Otherwise, public hospitals will become autonomous medical departments, with uncontrolled vested interest in curative medicine, that is to say, disease. Disease is negative and unproductive. It is in the interest of society to limit so far as possible all vested interests in social activities that are negative and unproductive in subject.

The recent passage of the Hill-Burton Act to give aid in adequate provision of hospitals and health centers, and the rapid increase in prepayment medical care plans make it desirable to define some of these commonly accepted terms for the sake of clarity in thinking. (1) *Adequate medical care* makes available to the community without discrimination all facilities of medical science necessary for the individual to achieve and maintain optimum health of mind and body. (2) Health of mind and body is a basic human need; a healthful community is a basic social need. *Public health* has as its aim the meeting of these needs. The program should not only include curative and preventive measures for the protection of the individual and the community against whatever interferes with the full development and maintenance of man's mental and physical capacity, but should go beyond these to the promotion of positive health through appli-

cation of sociological concepts and methods to the problems of health and disease. The October, 1945, *Newsletter* of the Commission on Hospital Care defines: "*Health centers* would provide facilities for health officer, nurse, sanitarian, physician, certain diagnostic services, and a few hospital beds for patients who could not readily be transported to larger centers or who would not require the services of specialists."

Tax units throughout the country are increasingly combining health administration and hospital care. This has already been done in California and Massachusetts and is planned for New York State. Unless the public health profession realizes its opportunity and responsibility, there is a real danger of community health being run by hospital administrators limited to a disease outlook.

Reference has already been made to the Bingham Associates, the Council of Rochester Regional Hospitals, and the Michigan Community Health Project. These plans call for an affiliation between the medical center and regional and community hospitals. The Rochester project is at too early a stage to permit comment, but the other two plans so far have been concerned predominantly with disease rather than with health, that is, training graduates in "diagnosis and therapy" of disease without any discernible concern with either rehabilitation or promotion of positive health. The direction of both the Bingham and Michigan plans is under clinicians. A possible reason for this exclusive concern may lie in the fact that planning is from the base hospital and center toward the community, rather than from the community, building up gradually in terms of needs, to the base.

As peripheral tax units administratively combine hospitals and medical care, there should also be integration

with the local health administration as already suggested. The most carefully designed proposal for this integration may be found in New York State. *The Schoharie County Health Service* (July, 1946) in the relationship between the rural hospital and the public health service states as its underlying principle, "It appears apparent that only through a program of combined action can there be an adequate service developed for the base of many of the more sparsely settled sections of the country." The plan makes the following proposals: The hospital is to be operated either as part of or in close coördination with the county health department and under the administration of the county health officer, who should have had experience or a short period of training in hospital administration. The hospital, in addition to providing space for the health department, is to provide offices for certain practitioners, particularly the surgeon, internist, and the pathologist, and roentgenologist on a part-time basis. The services of the part-time specialists, together with such other consultative services as may be required, will be in association with the Albany Medical Center. The nursing service of the hospital, its out-patients, and the field nursing service of the health department are to be coördinated through a joint plan by the hospital and health departments for the referral of patients, transfer of records, etc., to provide continuity of nursing care in accordance with patients' needs. The hospital is also to house the public health laboratory service. The United States is greatly in need of carefully planned regional experiments along this line to build up the experience required to plan for the needs of adequate medical care from the periphery to the base. However, the medical care will not be adequate in terms of our definition, unless the individual responsible for plan-

ning is health conscious rather than disease-minded.

Another development which may prove of national significance is the Maryland medical care program developing under the State Board of Health. This is the first state board to administer medical services to the indigent and medically indigent. Administration is decentralized under the county health departments with advisory councils. The significant features are the state-wide provision of clinical diagnostic services and, more particularly, the proposed consultation service with active participation of The Johns Hopkins University and the University of Maryland, which, in effect, would evolve into a program similar to that of the Bingham Associates *but* administered not by hospitals or a medical school but by the health department.

Hitherto the health services have assumed responsibility for "personal health services" because of their essential part in the prevention of disease. The general practitioner has in the main not undertaken preventive measures for two reasons: First, the exclusive emphasis in his training in diagnosis and therapy has not prepared him to undertake these preventive services, although rationally these should be as important a part of clinical medicine as diagnosis and therapy. This situation is gradually changing in obstetrics and particularly in pediatrics, but should be extended to all clinical medicine and should include rehabilitation and the application of knowledge of the social and economic factors concerned with health and disease. The second reason is fee-for-service, and the consequent economic deterrent on the community to seek preventive medical care. The recent separation in England of personal health services from health administration as such is rational and eventually will be universal, with the general practitioner

undertaking all required preventive medicine. This will require considerable reorientation of undergraduate medical education with respect to the teaching of preventive and social medicine. Similarly there must be a renewed reorientation in the training of public health personnel, particularly the health officer.

A major reason for the hesitancy of the health officer in the United States to assume administrative responsibility for medical care, including hospital administration—a hesitancy which does not obtain in any other English speaking country—is the lack of leadership in the schools of public health to foresee the future and to train the future leaders of the country in their responsibilities toward medical care administration. The health officer should have the same basic knowledge of medical care administration, including hospital administration, as he has had opportunity in the past to acquire in biostatistics and public health microbiology. Due chiefly to the help of the Kellogg Foundation, there are now six universities (three schools of public health) either offering or in process of establishing courses in hospital administration. In the current academic year 201* students are registered this academic year in the five schools already operating. The courses lead to a diploma or certificate. The balance of the field of medical care administration is practically ignored even in schools of public health. It is of interest to note that the London School of Hygiene is in process of reorganization, whereby one of its three major interests will be medical care administration. Only two of the schools in North America are in a position to offer even a major elective in the M.P.H., and then only in the economic aspects of medical care administration. It is

natural that health officers are hesitant to undertake the responsibility of medical care administration in advance of opportunity for training in the art of medical care.

Schools of public health should immediately inaugurate major departments of medical care administration, including medical economics and hospital administration. Training can more effectively be undertaken if the schools are in universities with a medical college associated organically with the community and district health centers and hospitals of the area in the manner already described. Similarly, the closer the department can be associated with the administration of prepayment hospital and medical service plans in the area, the more effective it will be. Investigation should be as important a responsibility as teaching. Such investigation would determine methods and techniques of promoting positive health on the one hand and, on the other, explore the most effective administrative methods and techniques for the distribution of medical care. Naturally, the closer the department is associated with the administration of medical care plans, the greater the opportunity for controlled investigation. Mere access to prepayment plans not controlled by the teaching department will prove unsatisfactory if only for the reason that in general this will mean access to inadequate medical care which the department will be unable to correct in terms of the principles it is teaching. Such association of academic departments to control teaching and investigative facilities has long been considered a necessity for pre-clinical and clinical medicine. It is no less a necessity for medical care administration.

SUMMARY

The United States is rapidly laying the foundation for a vast extension of medical care and health services. The

* One hundred and forty-two at Northwestern.

expansion of these services must be undertaken by a single administrative body for the whole community, not by several governing bodies. If adequate medical care is to be attained, particularly in its health aspects, this body should be public health administration. Health departments can ill afford to ignore the outstanding world trend in the organization of medical care and health services which is the regionalization of hospitals and their interrelation in each area in a unified plan to provide a two-way flow between the center and periphery for better medical care facilities, as well as for training and research.

It is now twenty years since Professor Winslow gave his presidential address, "Public Health at the Crossroads."⁵ In this statesmanlike discussion of the major problems of the Association for the succeeding fifty years he said: "The attempt to fix the boundaries of the public health program by establishing a distinction between prevention and cure must lead only to confusion and incertitude," and he called attention to the problem of making medical service really preven-

tive and not an attempted alleviation after the event. His summary challenged the health officer of the future to undertake the lead in governing the form and direction which inevitable extension of medical care would take during the succeeding twenty years. These twenty years have now transpired. The profession is even more at the crossroads today, because of the parting of the ways which will determine whether or not the primacy of preventive medicine is to be maintained by having health-minded, rather than disease-minded, persons responsible for overall planning and the direction and allocation of community resources. We should realize and seize this opportunity.

Discussion of Papers on The Health Department and Medical Care

C.-E. A. WINSLOW, DR.P.H., F.A.P.H.A.

Editor, American Journal of Public Health, and Emeritus Professor of Public Health, Yale University, New Haven, Conn.

DR. GRANT made a more than gracious reference to my Presidential address of twenty years ago. I deeply appreciate it. In discussing these papers, however, I do not wish to penetrate quite so far into the dim ages of the past; I want to go back only fourteen years to the report of the Committee on the Cost of Medical Care adopted in October, 1932.

That report recommended a policy of medical care embodying two general principles: the provision of such care "largely by organized groups of physicians, dentists, nurses, pharmacists, and other personnel . . . preferably organized around a hospital for rendering complete home, office, and hospital care"; and distribution of the cost of medical care "on a group payment

basis through the use of insurance, through the use of taxation, or through the use of both these methods." The committee specifically avoided recommending compulsory insurance at that time, but suggested gradual experimentation along the general lines laid down above. The principles outlined have now met with reasonably general acceptance. The gradual experimentation which we hoped might point the way, has, however, been long delayed, chiefly because the *Journal of the American Medical Association* denounced our proposals as "socialism and Bolshevism, inciting to revolution."

Today, however, such experiments as we visualized are being made and three such experiments of major importance have been described in the preceding papers.

The Maryland Plan attacks one sector of the general area of chaos in an interesting and promising fashion. It deals only with the care of the indigent and semi-indigent but this is at least a step in the right direction. There used to be a common slogan to the effect that "only the very rich and the very poor get good medical care." This was better than most slogans in so far as it was half true. In the past only the very rich received good medical care, but in Maryland the very poor are also placed in a privileged position. In one respect I think that the Maryland program is perhaps more a demonstration than an experiment. In experiments we generally start from the basis of well established facts. We do not begin to study the etiology of a disease like epidemic jaundice by first exploring the theory that this disease is caused by miasma. There is a vast body of evidence that any insurance plan based on fee-for-service payment is bound in the end to involve impossibly high cost. I do not, however, question the importance from a psychological standpoint of trying it out again,

and in many respects the experience of Maryland should prove of incalculable value to other areas.

The Health Insurance Plan of Greater New York is an experiment of wide significance and great promise. It is essentially, so far as the insured person is concerned, a compulsory health insurance scheme which is non-compulsory. However, when one realizes that the government of the City of New York and such private industries as join the program will pay approximately half the cost of medical care for the insured person and his family, it would be a rare individual who did not feel a self-compulsion to join. This program too, of course, covers only one section of the community, although potentially a major section. Many industrial firms will fail to participate and their employees and the self-employed will no doubt desire a similar program for themselves. It is of the greatest interest that the plan is based on group practice, and it is a fine tribute to the statesmanship of Dr. George Baehr that this program was adopted by the consent of the county medical societies. These societies first asked for a fee-for-service basis and individual practice. This proposal was accepted by the proponents of the program *but* only on condition that the county medical society should undertake to police the plan and keep its cost within limits. After months of conference, both sides agreed to group practice and capitation payments.

Dr. Jackson has told you of a wider program in Manitoba and Dr. Grant has given you a picture of world-wide trends in the same direction. I think it may be considered certain that in the United States, as in other countries, we must ultimately meet the demand that complete medical care, of the highest quality available in a given area, shall be accessible to all citizens and on terms compatible with their self-respect.

I agree with those who have urged a responsibility of the health officer in this vital health issue of the next decade. It is by no means necessary that he shall furnish medical care. The wise administrator is the one who "let's George do it" whenever "George" can perform adequately. The health officer is, however, the one individual who has direct responsibility to the community for all aspects of the health of the people, and it is his duty to see that in some fashion the ends outlined above are attained.

I agree with Dr. Grant that our schools of public health are not doing their duty adequately in connection with this vital responsibility of the community health administrator. It happens to be my privilege as consultant to the Committee on Professional Education of the American Public Health Association to visit and study the schools of public health. In nine schools which I visited last year there were thirty-five faculty members of professorial or associate professorial grade in the field which deals with microbiology, immunology, and epidemiology. One school only (Michigan) had a full-time faculty member to cover the field of social and economic factors in disease. These factors in a country like the United States are far more important than those which relate

to the spread of epidemic disease. I must, however, call attention to the fact that the schools of public health are struggling with a vast task and in all but two or three instances with relatively meager resources.

The papers which have been read here and the discussion which has followed are constructive and significant. We have a long way to go but we are on our way. The logic of facts is with us. I have learned through some years of experience that ultimately the thing that is logical and right will come to pass. The public is year by year getting a clearer idea of what good medical care may mean and it is more and more determined that such care shall be made available to all. Let me remind you of a tale which Professor Frank Graham of the University of North Carolina used to tell. He had a summer place on the seashore on very low land. He was there one weekend during a storm which produced almost a tidal wave, rising almost to the windowsills of the cottage. His colored cook was frightened, and he tried to reassure her by saying that he thought the water was going down. She replied, "Massa Frank, it ain't them three feet of water outside the window that I is a'feared of, it's the 3,000 miles of water that's leanin' up against it."

Today's Key to Better Public Health Service*

WILLIAM P. SHEPARD, M.D., F.A.P.H.A., AND
REGINALD M. ATWATER, M.D., F.A.P.H.A.

Metropolitan Life Insurance Company, San Francisco, Calif.; and Executive Secretary, American Public Health Association, New York, N. Y.

AT a recent symposium of state health officers and directors of local health service it was agreed that our most critical public health problem today lies in the shortage of trained personnel. Never before has there been such a demand for public health staff; never before such ambitious programs waiting to move forward; never so much agreement as to where the next steps should lead. But all of this is only frustrating when the men and women cannot be found.

At this moment there are on record with the American Public Health Association more than 800 openings of the better kind for doctors, engineers, health educators, laboratory directors, statisticians, industrial hygienists, public health dentists, school physicians, sanitarians, and others. We have listed fewer than 100 persons available to meet these urgent demands. There are very few other candidates available in the market. Even these country-wide listings do not exhaust the actual and potential vacancies which can easily be uncovered by talking to any public health administrator.

This represents a truly unprecedented situation. The ten schools accredited by the Association for the M.P.H. de-

gree are operating almost to capacity. There are about 500 enrolled for the M.P.H. courses and almost as many enrolled for other degrees and as special students. One would think that this gave promise of some relief by the time these trainees are through their courses. But the fact is that most of these individuals are already engaged in some public health capacity and will return to their assignments. Very few are available to meet the demand reflected in these figures.

There is little need for further documentation of this shortage which is known to all. It is imperative to look beneath the surface and to discover why careers in public health, which in the past have brought out some of the most able men and women, are today less sought after. Even ten years ago in the United States there was a distinct surplus of well trained persons with public health experience ready to take career positions. That reserve is nonexistent now. Shifting of experienced persons from one area to another does not alter the fact that the demand greatly exceeds the supply.

It was manifest at the recent National Conference on Local Health Units that state health officers and their directors of local health service believed that our inability to recruit professional personnel was the most difficult single obstacle to the extension of public health services. They went further to state that the most

* Presented before the Health Officers Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 12, 1946.

serious handicap in recruiting personnel was the unfavorable position of public health salaries compared with other professions requiring comparable education and training and compared with other positions open to persons trained in public health.

To come directly to the point, we need only to compare salary trends for various types of public health workers with recent increases in the cost of living to understand the situation. We are indebted to the State of Louisiana for charts showing that recent salary increases for different types of public health work average far less than the increase in cost of living. They also average less than the increases in farm wages, in manufacturing wages and, of course, are much less than the income increases of private physicians, engineers, and others at work in these communities.

A recent study made for the Committee on Postwar training of Public Health Personnel of the U. S. Public Health Service by Dr. George T. Palmer showed the mean of salaries for full-time physicians in state health departments to be only \$5,100 per year. The range was from a minimum of \$3,000 to a maximum of \$12,000 (in one instance). As long ago as 1943, *Medical Economics* found in a sampling of about 5,000 doctors that the average practising physician's net income was \$8,700 a year with a gross of \$13,600. It is now much higher, of course. We have long known that public health engineers were paid far less than their colleagues in other engineering fields, despite the fact that their training often exceeds that of civil, mechanical, and electrical engineers. Only recently, and then only in a few places, has the additional training of the public health nurse been recognized by slightly higher compensation. It is a notable fact that among public health workers as a whole the largest percentage increases have been to clerical

and technical personnel, and the lowest rates of increase to the professional classes.

It is obvious then, that public health workers are underpaid. This situation has arisen during a time when more than ever before there has been an increasing demand for high standards of training and experience. The health officer who seeks employment today on a career basis must offer far more than graduation from medical school and internship in a hospital. To fill a responsible position in most cases he will be required to present a Master's degree in public health, or its equivalent, representing not less than one year in residence at an institution equipped to give postgraduate courses in this field and a substantial amount of full-time experience under supervision. Physicians who wish to direct maternal and child health, mental hygiene, and cancer control programs may need as much as three years' graduate training after the internship. The public health nurse to qualify for the better positions needs to complete a year's course in an institution accredited for this purpose and have several years' experience. The demand for engineers with Masters' degrees in public health is definitely increased, and so it goes for other types of workers. The kind of education and practical experience that a young person needs to qualify himself has become generally accepted as evidenced by the American Public Health Association approval of some fifteen reports on desirable educational qualifications for the different categories of public health workers.

We believe you will agree with our conviction that, from this point on, energy which we spend in raising salary standards will do more to increase the number and improve the performance of public health workers than anything else we can do. Good personnel practices are important too and we shall continue and expand our studies in this

field through the Merit System Unit.

It is a fact that there is a linkage between the money income of a profession and its prestige. If public health is to demand from the physician, for example, a graduate and postgraduate training that requires as much competence and as long a preparation as that for the various specialties of medical practice, then in the long run the community must compensate the physician in public service in approximately the same way as the private practitioner. Failure to do so leads to the inevitable consequence of getting second quality physicians.

It seems to be true that most scientists—and public health scientists are no exception—are a notoriously modest lot. The professional worker has not been accustomed to parading his claims for higher compensation. Indeed, strict barriers of law and regulation are set up to prevent the degrading of the profession by such devices as advertising, which is an acceptable practice in most other fields. Now the time has come when professions without a clear recognition of the parallelism between adequate compensation and good service are taking the consequence of a pattern developed in a very different day.

Among the more than 10,000 members of the American Public Health Association approximately 36 per cent are graduates in medicine; other specialties in public health are the product of disciplines which similarly make abhorrent any suggestion of self advertising and of bragging in the market place of the achievements of their profession. We believe it to be self evident that this professional reticence has prevented the recognition of the true worth of the public health scientist in frank terms of money and the value of his services to the public in dollars and cents. Since none will speak for himself, we believe it to be a function of the public health worker's professional society to speak for him, and by every means in its power

to create public and legislative attitudes favorable to him. In so doing the man in the street will get better public health service.

What is the value of a health officer to a community? So far as we know there has yet to be computed the real money value of such a public servant to a community when he conserves the community human assets. If, however, one takes the decline in deaths from even the most obvious causes and computes the conservation of human resources by multiplying this number of saved lives by the worth of the man as computed by Dublin, there is a very high resulting value of the health officer in dollars and cents accruing to the community.

For example, in Great Britain in recent months it is reliably estimated that effective methods for the control of cerebrospinal meningitis among the civilian population have saved 15,000 lives. Even if the doctors and nurses and epidemiologists who accomplished this result, in coöperation with the private physicians, contributed nothing else to the welfare of Great Britain, they have made an astounding saving of material as well as human resources, especially during the critical wartime days when man power was at such a premium.

To be sure, those who contribute to the public welfare through preventive medicine work against a serious handicap in being unable to give the name and address of the person who did *not* acquire this or that disease because of successful preventive measures. The activities of these health men are characteristically unheralded and largely unknown to the public. The persistent supervision, for example, that a public health engineer will give to a municipal pasteurizing system, preventing the outbreak of milk-borne disease, suffers in dramatic comparison with the activities of practitioners who cut and dose their

patients. The extra effort that the public health nurse may make at the end of a long day to uncover a fresh case of syphilis in a promiscuous person may represent a contribution to the public welfare entirely out of proportion to the salary which she is paid. When followed through with curative procedures, this action may well prevent the birth of babies with congenital syphilis and the long continued custodial care of those who otherwise would have the central nervous system complications of this disease.

In short, we believe it is poor business and false economy on a national scale for the salaries of public health workers to remain low in comparison with the incomes of similarly trained servants of the public with whom there is an inescapable competition for top quality leadership. In our society at the present time the money rewards of those in business and industry are proportionately so great and are increasing with such rapidity that the individual with a public service motive finds himself at a distinct disadvantage. The notable increases in public income and the increasingly generous public response to national appeals for voluntary health agency work are reflected to only a slight degree in the compensation of the workers without whom these programs cannot succeed.

As we look ahead to the kind of world our children will live in, it is plain that we want our public services in the schools and in the health departments staffed by professionally adequate persons, attracted to their positions on a career basis and held there by a hard-earned professional competence. They need a firm conviction that their job is worth while and that it is appreciated. This can only be brought about by adequate compensation. If we can achieve these goals we can know for a fact that the educational and health status of our children and grandchildren will be far

better than if it is assumed that these services will be staffed only with those of second or third grade quality.

There already is a ferment at work on all sides in the service professions that demands quite vocally reasonable rates of pay. Teachers and social workers and some other professional groups are beginning to be unionized. We believe that the professional societies can accomplish better public support for their members than can trade unions, without the sacrifice of the professional ideals which we value so highly.

Difficult working conditions and inferior pay scales which have made words and phrases like "inequities," "equal pay for equal work," "fair employment, practices," etc., widely understood in other groups in the population, also exist among professional groups and must be realistically faced.

We believe that the use of wise compensation plans by the public as instruments of personnel management can result in correcting much of this deplorable situation. We believe that the federal agencies have been wise in urging state and local compensation plans which meet the test of good procedure. We believe with Mountin and his co-workers that these compensation plans should provide a recognition of the principle of equal pay for equal work; a fair adjustment of the salary range to the responsibility and difficulty of the work expected; a realistic recognition of prevailing wage levels for similar work in private industry and other public agencies in the locality, and recognition of the economic law of supply and demand in relation to current labor markets.

We now are seeing the operation of a very short-sighted public policy which in several states freezes compensation levels at figures long out of step with the current market value of the services. The penalty, of course, is that competent persons with training and experi-

ence are drained out of these areas of inadequate salaries into better paying areas.

The situation which has been so well dramatized in the shortage of teachers and of student nurses is facing public authorities and appropriating bodies in other respects and workers in the field of public health must not be overlooked.

The Committee on Professional Education of the American Public Health Association, after long dealing with this subject, has been advised by the Governing Council and the Executive Board that it ought to have no embarrassment in presenting, quite objectively, the inherent relationship between good standards and adequate compensation. The committee has begun a serious study of the salary situation. It has been determined that the Association will not spend its effort in putting on record evidence that salaries are below subsistence level in many categories and in many places. Everyone with insight knows that now. The committee has determined at this time that decent salary ranges shall be affirmatively recommended and that the committee will now state publicly the acceptable salary ranges for various types of jobs. This

we believe to be a real challenge to immediate action.

A committee has been appointed under the chairmanship of Dr. Leonard A. Scheele which held its first meeting at the Cleveland session. We believe that no long, detailed, statistical study will be needed. As a start, perhaps all that is required is a report which will bring together broad outlines and put the entire picture into focus for specific recommendations. We bespeak your coöperation with this committee which may call on many of you for assistance. Your professional society; the American Public Health Association, can do more than we as individuals can do and the Committee on Professional Education will provide all the help within its power. Much will depend, however, on the aggressiveness, determination, and persistence with which our recommendations are supported by you who are administratively responsible for the quality and performance of your staffs. Either you and we must represent their best interests or they will be forced to do one of two things. They will either forsake public health to the great detriment of the public, which they are already doing, or they will organize to represent themselves.

Universal Serologic Reactivity with Lipid Antigens^{*†}

Basis for "False Positives"

REUBEN L. KAHN, Sc.D.

*Serology Laboratory, University Hospital, University of Michigan,
Ann Arbor, Mich.*

A SEROLOGIC phenomenon with lipid antigens has been observed in this laboratory which has seemed to us unique. It has been observed that lipid antigens that are highly specific in the serology of syphilis may be technically so employed with sera as to give nearly 100 per cent positive reactions without regard to syphilis. These reactions have been referred to as "universal reactions" because they can be elicited in almost all human beings and in animals under a variety of technical conditions. These universal reactions will be briefly considered in this article. Major consideration will be given to a relationship which apparently exists between universal reactions and false positives encountered in the serodiagnosis of syphilis. Data will be presented indicating that false positives have their origin in universal reactions.

Universal Serologic Reactions

It was previously reported from this laboratory¹ that tissue extract antigens can be prepared of such high sensitivity that they give nearly 100 per cent precipitation reactions and, to a somewhat

lesser extent, complement-fixation reactions with sera from non-syphilitic human beings. Present studies indicate that close to 100 per cent precipitation reactions, referred to as universal reactions, can be obtained also with sero-diagnostic antigens provided appropriate technical conditions are maintained. The lipid extracts employed in eliciting universal reactions were Kahn standard, Kolmer and cardiolipin antigens.

Table 1 presents universal reactions with ten sera. The deviations from the standard Kahn procedure were that the salt solution used as diluent after the 3 minute shaking period consisted of 0.3 per cent NaCl solution instead of 0.9 per cent, and the tests were read after 24 hours' incubation in the icebox instead of immediately after the addition of diluent. It is evident that nine of the Kahn-negative sera gave positive reactions under the modified conditions, and the tenth serum was positive when sensitized antigen, instead of standard Kahn antigen, was employed. It might be added that these precipitates were found to be dispersible upon the addition of 0.1 ml. amounts of a 5 per cent NaCl solution to the tubes.

Table 2 presents universal reactions with Kolmer antigen. The modified tests were performed at 1° C., employing the usual Kahn serum:antigen ratios and the 3 minute shaking period; but

^{*} Presented before the Laboratory Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 12, 1946.

the diluent was omitted. All of the Kahn-negative sera showed precipitation reactions. These were reduced on the addition of diluent.

Table 3 presents universal reactions with cardiolipin and Kahn antigens. When the tests were performed at 1° C. with either antigen, and without shaking, all sera showed some precipitation reactions. After the 3 minute shaking period and the addition of diluent, the reactions became negative.

Table 4 illustrates universal reactions quantitatively. Serial dilutions of Kahn-negative sera were prepared with

0.3 per cent NaCl solution. The dilutions ranged from 1:2.5 to 1:160. Standard Kahn antigen was employed and the tests were carried out according to the Kahn quantitative technique except that 0.3 per cent NaCl solution was employed as diluent and the tests were read after 24 hours' incubation in the icebox. It is evident that wide variations exist in the precipitation results given by the different sera. One serum (No. 3) gave strongly positive results in all the serial dilutions employed.

tions is the dispersibility of the precipitates by strong NaCl concentration. As already indicated, 0.1 ml. amounts of 5 per cent (or higher) NaCl solution added to the precipitates will generally cause their dispersion within a few minutes.

*Certain Optimal Technical Conditions
for Eliciting Universal Reactions
Are Optimal Also for Eliciting
False Positives*

The data presented above indicate that positive reactions with non-syphilitic sera can be brought about by the use of different technical steps and with different antigens ordinarily used

in the serology of syphilis. A technical step common to the tests listed in Tables 1-4 is the use of cold temperature, either in the performance of the tests or in their incubation. Another technical step which favors universal reactions is low NaCl concentration in the precipitation system. Also common to the universal reactions listed is the dispersibility of the precipitates in strong salt solution.

These three features form the basis of the verification test devised in this laboratory as an aid in the detection of false positives.² When sera giving these positives are examined with the differential temperature technique of

TABLE 7

Specific Reactions in Syphilis, Universal Reactions and False Positives in the Absence of Syphilis—Employing the Same Lipid Antigens

Specific reactions	Obtained with serodiagnostic tests restricted to syphilitic reactions—but occasionally giving false positives.
Universal reactions	Given by practically all sera, with various techniques (different from serodiagnostic tests) including those based on the following three characteristics: low salt concentration, low temperature, and dispersibility of precipitates.
False positives	Generally show optimal reactivity at low salt concentration and low temperature, and the precipitates are dispersible.
Universal reactions in relation to false positives	Since low salt concentration, low temperature, and dispersibility of precipitates are characteristics of techniques giving both universal reactions and false positive reactions (and not of serodiagnostic tests), it is believed that false positives are highly potent universal reactions which have crossed the serodiagnostic threshold. Briefly, it is believed that certain non-syphilitic sera possess such marked universal serologic reactivity that they tend to give positive reactions even with tests that are technically restricted to the detection of syphilis.

perature, and the precipitates are dispersible. The controls, which consist of two syphilitic sera, show maximal reactivity at 37° C. and the precipitates are not dispersible. Table 6 illustrates typical false positive reactions with two sera in which maximal reactivity is noted under conditions of low salt concentration, and the precipitates are dispersible. The syphilitic serum control gives maximal reactivity under conditions of increased salt concentration and the precipitates are not dispersible.

RELATION BETWEEN UNIVERSAL REACTIONS AND FALSE POSITIVES

Is there a direct relationship between universal reactions and false positives? In Table 7 an attempt is made to correlate this relationship. It was seen in Table 4 that different sera show quantitative differences in universal reactivity and some show especially marked reactivity. It is believed that such sera, as for example Serum No. 3 in that table, may possess sufficient reactivity to break through the threshold of the serodiagnostic test. The technical barriers of modern serodiagnostic tests exclude the vast majority of non-syphilitic sera from reaching positivity, but it is believed that those sera which possess extremely high universal reac-

tivity do reach positivity with these tests and give false positives.

Chart 1 illustrates the concept that false positive reactions with serodiagnostic tests represent universal reactions of such high potency that they pass the serodiagnostic threshold. As already indicated, universal reactions can be elicited by different techniques. For illustrative purposes five techniques have been chosen, although it is believed that further studies will show that additional techniques could be developed for eliciting universal reactions. When the five chosen techniques are employed with non-syphilitic sera quantitatively, by determining the highest dilutions of serum which will give positive reactions, it will be found that each technique shows distinctive reactivity. The five techniques applied to six sera are represented in the chart by five columns for every serum, and the height of each column represents the reactivity of the particular technique employed. The heights of the columns differ because an individual serum may show quantitatively different reactivities with the different techniques.

The reactions of Serum No. 1 are confined to the region of universal reactions and are below the serodiagnostic threshold. Columns 2 and 4 reach close

CHART 1

ILLUSTRATING THE CONCEPT THAT
FALSE POSITIVES ARE UNIVERSAL
REACTIONS WHICH HAVE CROSSED
THE SERODIAGNOSTIC THRESHOLD

to the threshold, but remain below. In the case of Serum No. 2, column 1 passes the serodiagnostic threshold. Stated differently, Serum No. 2 examined with technique 1 manifests such marked universal serologic reactivity with serodiagnostic antigen that the same serum examined with the technically restricted serodiagnostic test will also manifest some degree of reactivity, and give a false positive. In the case of Serum No. 6, it is column 4 that passes the serodiagnostic threshold, and that serum also will give a false positive reaction.

It is noted from the chart that the difference between the height of those columns which approach the serodiag-

nostic threshold and those which pass the threshold may be small. This critical difference in the reactivity of universal reactions close to the threshold helps to explain the fluctuating tendency frequently encountered in false positive reactions. It is well known that false positives may occur one day and be gone on repetition. Since minor quantitative differences in reactivity in the vicinity of the threshold are sufficient to change a reaction from negative to positive and *vice versa*, it is understandable why false positives show a tendency to fluctuate.

It is also understandable why most false positives are weak serodiagnostic reactions. With universal techniques

the reactions are very strong as is evident from the height of the columns which reach into the serodiagnostic region. But serodiagnostic techniques are designed for the detection of syphilis and they are unfavorable to reactivity in the absence of syphilis. These techniques are indeed so restrictive that the vast majority of sera giving universal reactions are completely negative with serodiagnostic tests.

It must be kept in mind that the serodiagnostic threshold is not identical for all serodiagnostic tests. The more sensitive the serodiagnostic test, the lower is its threshold, i.e., the larger the number of universal reactions that will cross its threshold. Hence, a super-sensitive test will give a greater number of false positives. Occasionally, two tests of similar sensitivity will yet differ in giving false positives in individual cases. Apparently, the mere

fact that a column of the universal reaction enters into the serodiagnostic region does not necessarily mean that it will cause a positive reaction with all tests. This difference is very likely due to different characteristics of the tests.

It would appear from the chart that false positives are not "false" but are offshoots of serologic reactions occurring on a biologically universal scale. The chart also points out the importance of emphasizing not increased sensitivity but increased specificity in serodiagnostic tests. For, when sensitivity is stepped up, the threshold is lowered toward the universal reactions and specificity is reduced.

Different Types of False Positives

If, according to Chart 1, any one of the universal reactions, as represented by the individual columns, can potentially cause a false positive, it must be

assumed that there are different types of false positives. One type might be caused by a particular universal reaction and another type by another reaction. Actually, long before we observed the existence of universal reactions, we recognized that there are different types of false positives detectable by different techniques, which explains the three techniques of our verification test.²

Tables 8 and 9 present illustrative cases of false positives, taken from our routine laboratory records, which show that these positives represent more than one type of reaction. In Table 8, the false positives are characterized by optimal reactivity at low salt concentration and in Table 9, by optimal reactivity at low temperature. Generally, false positives show optimal reactivity both at low salt concentration and at low temperature, but some show reac-

tivity at only one of these conditions.

An aspect of universal reactions and of false positives which has not been included in the tables is that different sera show different serologic patterns with given techniques. This aspect will be considered in a later publication.

Experimental Evidence That Certain False Positives Are Universal Reactions Which Have Crossed the Serodiagnostic Threshold

Table 10 presents an illustrative experiment in which universal serologic reactivity is demonstrated with three sera: one giving a false positive reaction with a serodiagnostic test, another a negative reaction, and a third, a true or specific positive reaction. The sera are serially diluted with water, with 0.3, 0.6, and 0.9 per cent NaCl solution. These dilutions are mixed with Kahn antigen suspension in a ratio of 6:1.

shaken 3 minutes, and diluent added of the same NaCl concentrations used in making the serial dilutions of serum. The results are then read without incubation and after 4 and 24 hours' incubation in the icebox.

It is evident from the table that the universal reactions are most marked after incubation. On examination of the results without incubation, it is noted that non-syphilitic serum A gives most marked reactivity in the serial dilutions of serum with water, less marked reactivity in the serial dilutions of serum with 0.3 and 0.6 per cent NaCl

solution, and least reactivity in the serial dilutions of serum with 0.9 per cent salt solution. This 0.9 per cent column is, of course, identical with the middle tube of the standard Kahn test. It is obvious, therefore, that the two plus reading in this column represents an overflow of the universal reaction into the serodiagnostic zone. Non-syphilitic serum B does not show this tendency to reach the 0.9 per cent column. The syphilitic serum C, however, shows most marked reactivity in this 0.9 per cent column, and very little reactivity in the water column. After

incubation at cold temperature, the results represent universal reactivities only.

It might be added that the false positive serum A in the table was obtained from a serviceman who had recently returned from the Pacific area, presumably with malaria.

In view of the fact that there are different types of false positives, the data in Table 10 cannot be taken as proof that all false positives represent spill-overs of universal reactions into the serodiagnostic zone, but it would seem reasonable to assume that the same holds true to all false positives.

SUMMARY

1. Data are herewith presented showing that lipid antigen and serum employed in tests for syphilis can be so treated technically as to elicit positive precipitation reactions in most non-syphilitic persons. These reactions are referred to as universal serologic reactions because they are biologically widespread. Universal reactions differ from serodiagnostic reactions in that the latter are technically restricted to the detection of syphilis.

2. Universal reactions can be elicited in serum-lipid antigen combinations under a variety of technical conditions.

Low NaCl concentration and low temperature are optimal in eliciting these reactions, and the precipitates formed are generally dispersible in concentrated NaCl solution.

3. Low salt concentration and low temperature are also optimal for false positive reactions, and the precipitates formed are generally dispersible in concentrated NaCl solution.

4. The fact that the same technical conditions are optimal for universal and false positive reactions suggested a close relationship between these two reactions, and the concept that false positives are highly potent universal reactions which have passed the serodiagnostic threshold and have become manifested with serodiagnostic tests.

5. In agreement with this concept, an illustrative case of a weakly false positive reacting serum, is presented in which the universal reaction is of such high potency that it reaches into the serodiagnostic zone and shows positivity in that zone.

Colorado Tick Fever*

LLOYD FLORIO, M.D., DR.P.H., F.A.P.H.A., AND
MABEL O. STEWART

*Department of Public Health and Laboratory Diagnosis, University of Colorado
School of Medicine, Denver, Colo.*

DISEASES have occasionally been given geographical names, such as Rocky Mountain spotted fever, because they were originally thought to be limited to sharply circumscribed areas. With the dissemination of information concerning such diseases, it has usually been found that their distribution is much more cosmopolitan than was once supposed. This might also be true for Colorado tick fever, a disease frequently recognized in Colorado and occasionally in other Rocky Mountain states. The larger number of cases diagnosed in Colorado can be explained by the interest created by Becker¹ who described it as a distinct disease entity and who gave it the name by which it is now known.

EPIDEMIOLOGY

Individuals with Colorado tick fever practically invariably give a history of being bitten by the wood tick, *Dermacentor andersoni* Stiles. In every instance, the patient has been in a tick infested area 4 to 6 days prior to the onset of the illness. The disease, like Rocky Mountain spotted fever, is found only during the spring and early summer when the ticks are active. As soon as it becomes hot and dry, the wood ticks disappear and so does Colorado tick fever. Although experimental

work on the epidemiology of the disease still continues, the wood tick has been found to be naturally infected.² Laboratory studies indicate that the infectious agent is transmitted transovarially to at least the next generation of adults.²

CLINICAL

The onset is sudden and characterized by chilly sensations and a generalized aching of the whole body. Headache, deep ocular pain, and backache particularly in the lumbar region are the prominent symptoms. Photophobia is relatively frequent. Anorexia, nausea and sometimes vomiting are common. With the onset of symptoms, the temperature begins to rise and within 24 hours is usually between 102° and 104° F. There is a corresponding elevation of the pulse rate. The attack lasts for approximately 2 days. The temperature returns to normal, the symptoms completely disappear, and the individual feels well enough to resume normal activity. This symptom-free phase of approximately 2 days is followed by a recurrence of the symptoms and fever of about 3 days' duration. Convalescence is characterized by mild weakness and lassitude lasting 3 to 7 days. Single and triple attacks are occasionally observed. While periods of attack, remission and attack usually last approximately 2 or 3 days, each may vary from 1 to 4 days. Either attack may be more severe than the

* Presented before the Epidemiology Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 14, 1946.

other. During the remission, it is common for the temperature to be subnormal.

Conjunctival injection and mild erythema are the usual and only physical findings other than the elevation of temperature and pulse rate. Exanthemata are never observed. Complications are unknown, nor is the disease ever fatal. Treatment is purely symptomatic. Aspirin and codeine suffice in the alleviation of symptoms.

The only significant laboratory findings are related to the white blood cells. Beginning with the onset of symptoms, there is a progressive decrease in the number of leucocytes which usually reach the lowest point at the beginning of the second attack. Typically the white blood cell count falls to between 2,000 and 3,000 cells per cubic milli-

meter, although one as low as 1,200 has been observed.³ All of the leucocytes are reduced in absolute numbers except the monocytes. There is a definite shift to the left in the polymorphonuclear neutrophils. It is common for the band forms to outnumber the segmenters when the count is lowest. Four to 7 days following clinical recovery, the white blood cell and differential counts have returned to normal.

The differential diagnosis is not difficult. There are no other diseases occurring in the Rocky Mountain region with which Colorado tick fever can be confused. The history of exposure to ticks, the saddle-back temperature curve, the symptoms, and the white blood cell picture have made the diagnosis obvious after 4 or 5 days of observation. Figures 1, 2, and 3 depict

FIGURE 1—A Naturally Acquired Case of Colorado Tick Fever

* Schilling hemogram not done

FIGURE 2—Colorado tick fever in an experimental subject

FIGURE 3—Colorado tick fever in an experimental subject

the history, physical findings, temperature curve, and white blood cell findings in three instances of the disease.

Reinfection with Colorado tick fever has never been reported. Three volunteers were inoculated with a different strain of the infectious agent 9 to 12 months after the original infection.³ They did not develop the disease.

ETIOLOGY

Previous attempts to visualize the infectious agent of Colorado tick fever microscopically or by culture had been unsuccessful as had all previous attempts to induce infection in experimental animals.⁴ We were able to infect the golden hamster (*Cricetus auratus*).^{3, 5} Filtrates from gradacol membranes of known porosity were tested on these animals and it was established that the infectious agent is an extremely small virus of a particle size approximating that of yellow fever and poliomyelitis.⁶ Kaprowski and Cox⁷ have recently reported the adaptation of the virus to mice and to developing chick embryo.

RELATIONSHIP OF COLORADO TICK FEVER TO ROCKY MOUNTAIN SPOTTED FEVER AND DENGUE

Because Colorado tick fever is transmitted by the same vector as Rocky Mountain spotted fever, there has arisen a belief that this disease is a mild manifestation of Rocky Mountain spotted fever. Immunization against Rocky Mountain spotted fever does not protect against experimental³ or naturally acquired⁸ Colorado tick fever. Two cases of individuals who had had both diseases have been brought to our attention.⁹ Another is reported by Shaffer.¹⁰ Finally the fact that Rocky Mountain spotted fever is due to a Rickettsia while Colorado tick fever is caused by a virus, establishes these diseases as separate clinical entities.

The striking clinical and hemato-

logical resemblance to dengue, however, has caused various investigators to wonder whether Colorado tick fever might not be tick-borne dengue. The lack of a rash in Colorado tick fever, and the absence of a prolonged convalescence, are the important clinical differences. Since both diseases confer at least a short immunity to themselves, each should confer immunity against the other if they are identical. The problem was resolved by inoculating human subjects first with the virus of one disease and, after a period long enough to develop an immunity, with the virus of the other. They developed both diseases, indicating that the two conditions are probably distinct entities.¹¹ Using essentially the same technic, Pollard and his coworkers confirmed these results.¹²

SUMMARY

Colorado tick fever is a tick-borne viral disease, confined as far as is now known to the Rocky Mountain region. It is characterized by generalized aching, a saddle-back temperature with complete disappearance of symptoms during the remission and a markedly reduced white blood cell count with a shift to the left. The disease confers a definite immunity. Neither death nor complications occur. Treatment is symptomatic. While clinically and hematologically similar to dengue and often assumed to be a mild form of Rocky Mountain spotted fever, Colorado tick fever is a distinct disease entity.

The Nurse's Rôle in Health Education in Industry

BETHEL J. McGRATH, R.N.

Powers Dry Goods, Inc., Minneapolis, Minn.

"The application of the gifts of science is now more important than their increase."

IN his autobiography Clarence Darrow observes, of the tenacity with which man clings to life, "I sang hymns (as a boy) that I remember to this day. Among them was one which each child loudly shouted 'I want to be an angel and with the angels stand; a crown upon my forehead, a harp within my hand.' . . . I sang it earnestly and often, but in spite of my stout and steady insistence 'that I wanted to wear wings, here I am at 75 still fighting to stay on earth.'" The fight is universal but few remain in the battle at 75. Our weapons are not good enough or our strategy is poor. In spite of the fact that man values life, *this life*, above all else, his efforts to vitalize and prolong it are largely haphazard.

The first world war disclosed an appalling number of young men in poor physical condition. Something was to be done about it. The second world war also disclosed an appalling number of the next generation in poor physical condition. Whatever had been done during the interim to build health and prevent disease had not been enough. Sufficient scientific information was available to either generation which, if applied, would have resulted in a better health record. Are large numbers of our people economically unable to maintain a healthful standard of living;

foolishly optimistic about their chances of survival regardless of how they live? Have they never heard the facts; or if they have, has the information been given at a time, or in such a fashion that it has failed to impress them?

Early and constant exposure to health education through maintenance of community health services that begin with prenatal care and teaching, and continue through the preschool, school, and young adult groups, naturally has its effect upon the health level of the employed population of a community. However, not too much can be expected of a particular local health program by employers of labor because the population is constantly shifting; and highly industrialized areas draw from all parts of the country as well as from foreign countries. Standards and facilities in both the fields of education and public health differ greatly between communities, and inhabitants of many areas are exposed to little of either.

The natural optimism of youth, absorbed with living and unconcerned with dying, operates against the acceptance and use of much information that is presented during high school and college. Inadequate methods of presentation, and failure to develop athletics within the school for *all* to participate in, instead of only a few, both render the health education and physical fitness programs of schools much less effective than they should be.

Whatever may be the underlying causes, large segments of our population reach wage earning status either uninformed, or unimpressed with facts essential to health practices. This may mean the difference between a long and a short span of useful years, with all that it implies to the health and security of their dependents. Nurses who recognize the seriousness of this unawareness among young adults, and the parents of growing families invent ways to overcome it. Much of the worth of an industrial nurse to her company and to the community lies in her awareness and inventiveness.

There are sizeable obstacles to group educational work on the job which will not be overcome for a long time, if ever. Few employers sufficiently realize the value of sound health instruction to pay workers for taking it. Employment personnel, charged with keeping down labor costs, naturally are loath to authorize paid time spent at something other than job performance. Department heads, in need of workers are intolerant of anything that interferes with getting them on the job as fast as possible and keeping them there. And a natural antipathy to "classes" on the part of the working population is a more potent factor than any of the above. When adults choose to attend classes these are as a rule something of a vocational nature which will advance them in the kind of work they are doing, or teach them a trade or profession which they prefer to their current employment.

A primary objective of young workers tasting independence for the first time is to escape from all of the restrictions placed upon children. They want to eat what they like, wear what they wish, go where they please, make lots of money and spend it as they like and, God willing, they do. Escape from classrooms is one of the freedoms they cherish most. Resistance to on-the-job classes in subjects unrelated to their

special skills is about the same whether the worker is an eighth grade graduate or possessor of a college diploma. The latter feels frequently that he needs nothing the nurse can offer except medicine for a headache, although his knowledge of health protection is seldom on a par with his other attainments.

The point of lowest resistance to group health instruction on this obstacle course is during the orientation and training period of new workers. Almost any personnel or training director will spare ten minutes out of the time allotted to the new workers' introduction to the job for a health talk by the nurse, particularly if the talk is outlined so that the value of points which are to be made is obvious. This is the strategic time to gain the attention and coöperation of workers because they are facing a new job, and a new set of circumstances with prospects of success not heretofore achieved. They are open to suggestions that may help them get a right start. They have not yet learned the flaws in the organization which later may keep some of them from accepting even that which is good. They have not been coached by careless or maladjusted coworkers. And it increases their feeling of job security to learn early and at first hand that the nurse is an intelligent and considerate person, whom all may consult freely for the benefit of themselves or their families.

If employees are hired singly the nurse's introduction to the plant's health facilities will be done in an individual interview. However, if two or more are trained at the same time, which is usually the case, it is only a matter of good business to discuss topics which are of common interest to all in a group, since this arrangement conserves the time of both the nurse and the workers. Some time after this group conference, and before or very shortly after the worker goes on the job, there should be an individual confer-

ence between the nurse and each worker. During the group conference the class should be told that each will have an opportunity later to discuss in detail subjects introduced briefly in the class, or to ask for information in matters that are of interest only to the individual and not to the group. The individual interview with all new employees, following the group conference, gives the nurse an opportunity to become acquainted with each personally, to learn a little about the kind of person he is, and where emphasis must be placed to help him most, if help is needed. The employee has an opportunity to become acquainted with the health service, not as a patient, but as a visitor.

There is not room here to discuss the variety of topics that might be discussed with employed groups if circumstances require them and management and workers want them. Current texts on the subject carry detailed accounts. But if the employee is never summoned to another class during his working life, the introductory group conference, and ensuing individual conference, have built the foundation upon which well rounded health education of the worker, at work, can proceed. If this early two way approach is lost the same opportunity does not come again.

When preparing for the introductory health class (or health education conference) one must take into consideration at least the following factors:

1. The time allowance is likely to be short. One must condense facts for presentation so the talk does not seem hurried. Be explicit.

2. In this original talk, cover topics that are obviously of sufficient value to the individuals to hold their attention. The nurse's enthusiasm for the topic under discussion must be such that it communicates itself to the hearers. Droning through a routine speech wastes time for everyone. Respect for the independent status of the members of the group is part of the nurse's equipment. The workers' jobs do not depend upon passing

marks in health education. No form of coercion is possible. They will not fail if they leave the class without knowing a word that has been said. If they take anything away with them it is because the nurse has the ability to stimulate their interest and hold their attention. Whether she has this ability depends upon how much she wants to have it and how hard she works to acquire it.

3. She must strike a balance between underestimating the intelligence of the group, and taking for granted that what is common knowledge to herself is also to others. This must be borne constantly in mind throughout the nursing program and not confined to the original lecture.

4. It is necessary to have specific information for workers on specific jobs. If the class is a mixed group of men and women, or workers on widely differing kinds of work, some of the more personal aspects of job health may have to wait for the personal interview. As a rule a good deal of it can be handled in the group session.

Assuming that this introductory health class is an innovation, time will probably be allowed for only the briefest introduction to the plant's health facilities, which may consist chiefly of the nurse and her work. However, if one looks around there are a good many factors in the most humble organization that contribute to health and morale. The following outline may suggest points to be covered in a plant of a few hundred with full-time nurse and part-time physician.

1. Medical and Nursing Service

- a. Location and hours.
- b. Day and hour of the doctor's visits.
- c. Routine followed in reporting all accidents.
- d. Routine followed in reporting off for illness, and upon return to work following illness.
- e. This health consultant service is here to be used freely by all. Better to use it early and often than to wait too long. Much less wasteful of time, money, and comfort to prevent than to cure.

2. Employees' Cafeteria

- a. Hot midday meal at cost, containing all necessary food elements for balanced diet. This is of especial value to those who eat all meals away from home.
- b. Balanced diet better for one than vitamins by the bottle and much less expensive.
- c. A heating plant functions efficiently only when properly fueled, and the body when well fed. More information on food in

relation to health and efficiency in the nurse's office and on bulletin boards.

3. *Recreation Facilities*

These may be extensive or limited to a ping-pong table or a girl's club, or less. However, almost any organization that wants it now has its bowling team, base ball club, golf tournaments, hikers' club, chorus orchestra, or band. Almost any type of recreation that two or three have the interest to sponsor and push will bring followers because there is naturally a wide diversity of interests among adults.

These activities may be mentioned by the personnel or training director, but repetition that ties them in with health is desirable. The wrong kind of fun results too often in poor physical condition and the loss of a job. Many workers new to the urban area feel strange and alone and develop the habit of hanging out in beer parlors, drinking more than is good for them, and gambling, because no one has ever suggested that they do anything better. Diversions that keep inhabitants of cold climates out of doors during short summers should be stressed.

4. *Group Sick Benefits and Health Insurance*

The world is so full of these that the average individual is confounded by them. The genuine benefits of a plan can be told in about three sentences, and explained at greater length in the individual conference. (Unfortunately many of these have little to recommend them, but since non-profit hospitalization has taken hold, other forms of economic protection in sickness are improving in quality.)

These plans deserve much more attention than they get from many persons concerned with industrial health. One can vaccinate against smallpox, but not against appendicitis, or hundreds of other conditions that cost heavily. Inexpensive insurance against sickness is the average man's vaccination against ruinous costs in a crisis. (Most of these plans could and should give better coverage than they do.)

5. *Sources of Information*

Stress the importance of watching the bulletin boards for information on current events of all kinds in the plant and in the community. A large, well placed and well lighted bulletin board which carries an ever changing variety of information on such things as housing, sports events, extension classes, community agencies, theater, concerts, and other amusements, safety, nu-

trition, disease prevention, lost and found, and special items about the business that will interest workers, will naturally attract a great deal more attention than a board devoted to health and safety alone.

Accustomed to large colored posters, it is wise to vary the routine occasionally by posting an important item in fine writing. Almost everyone will examine it closely to see what it says. On any item concerning health always refer workers to the nurse for further details. Make announcements brief and to the point. Long strings of words, however beautifully grouped, get in everybody's way. Few will follow through to get the gist of the announcement.

The epidemiologists' presentation of health protection would cover many things not mentioned here, and probably few of those which are. Their contribution to science underlies the world's security against devastating epidemics. But this initial address to new workers is not as a rule the place to discuss control of contagious diseases. Adults have all heard of immunization and have either accepted or rejected it and are bored by it. There are ways of presenting it later which will not bore them. This is one of the important reasons for directing attention to the bulletin boards. During this initial address one emphasizes items of immediate advantage to the worker on the job, things that are available for his benefit within easy reach.

During the initial ten to thirty minute talk the nurse has begun the health education process within industry by explaining the uses of the medical and nursing service, the advantages of the in-plant food service, opportunities for recreation that are both healthful and enjoyable, inexpensive group protection against high costs of sickness and its attendant worries, and has ended by focusing attention upon the bulletin board as a reliable source of up-to-date information in most things that affect daily lives. Each of these is a positive service which can offend no one, regardless of religious beliefs or personal

antipathy to the subject of disease. Together they contribute immeasurably to the health and security of the workers and, intelligently managed, each carries on its own kind of health education.

Following the introductory health talk (or talks) the nurse's most effective educational work is done in her daily contact with individual workers. In these the nurse is not obliged to generalize at all. She can get down to facts pertinent to the one person in the picture at the moment. His interests, abilities, peculiarities, religious and family background, and anything else that goes to make up his particular set of circumstances can be given due consideration. He is receptive because he has come seeking information or counsel, and because he receives the undivided attention of a specialist in the health field.

The same topic discussed with several people may be handled differently each time. The facts of the matter are unchanged, but fitting them to circumstances which differ with each individual requires an adaptability of presentation that is wholly impossible in group teaching. Then too, many of the problems for which adults seek help are the kind that they would not discuss with a third party present. Altogether it is a good thing that industrial organization lends itself more readily to individualized health service than to mass instruction.

A recent poll of experts in the field of education produced the following conclusion (among others), "There should be more effort to deal with the needs and ability of each individual student. One of the curses of our school system has been too much standardization in the

treatment of all students, regardless of their immense differences in abilities and interests." This "difference in ability and interests" continues through life and is apparent throughout any industry, even between workers at the same bench. It is fortunate for both the nurse and the worker that circumstances favor the opportunity for her to deal separately with the "needs and abilities of each individual." There is much talk of treating people as persons. Here is where it is done.

On-the-job health teaching cannot supply what was omitted or poorly taught as the worker grew. It cannot undo the effects of superstition and misinformation which have undermined the health of many before they are employed. It can partially compensate for these errors by making available a fund of information for receptive adults which may enable them to overcome early handicaps and do better by their children than they have been done by. It can refresh the memory of those who have learned, but have forgotten. One cannot expect too great a holdover on any subject, including health, without an occasional refresher. It can keep workers informed of the advances in things to be done, that build and protect health, and stimulate their interest in securing these advantages for themselves and their children.

Studies of the Effect of the Provision of Good Housing on Health*

IN considering the question of health and housing relationships, a first essential is to define terms. The objective of the housing movement today is the provision of good homes (meeting the requirements of healthful, safe, and comfortable living) in a wholesome physical environment (providing openness, indoor and outdoor space for recreation and play, and other essential amenities, and with freedom from excessive noise, dust, and traffic hazards). Conversely, bad housing means substandard structures, substandard occupancy, or a substandard physical environment. The objective of the public health movement is not just the prevention and cure of disease. It is, rather, the promotion of optimum physical and mental efficiency and well-being.

Regarded in this light, the relation of housing to physical and mental health may be said to be beyond dispute. Probably no accepted public health authority would question it. In fact, the Committee on the Hygiene of Housing of the American Public Health Association has in its *Basic Principles of Healthful Housing* set forth thirty ways in which housing does affect health, together with specific recommendations as to how the essential health principles can be achieved in the provision of housing.

Therefore, what we need is not more evidence that housing affects health in a general way, but rather scientific evidence as to whether housing has spe-

cific and measurable effects and, if so, how such effects can be measured. Until comparatively recent years, projects that provided good homes in a good neighborhood were few. Now, we have many such public projects for low-income families and some private projects for middle-income families. Several studies have already been made, and there will undoubtedly be many others undertaken in an effort to demonstrate the specific effects of the provision of good housing on morbidity and mortality or on both. To isolate the factor of housing and physical environment from other factors affecting health is fraught with difficulties. Much careful thought has been given to this phase of the problem, and one or two scientifically based studies of limited scope have been made. Most published reports on the specific effects have not succeeded in segregating factors other than the physical environment and, as a result, their conclusions can properly be challenged.

GENERAL PRINCIPLES

In considering studies of the specific effects of housing on health, it may be pertinent to state certain general principles:

1. The case for proper housing for our people does not depend upon definite evidence that the provision of good homes in good neighborhoods lowers death rates or reduces sickness. It has ample justification in the democratic principles that people are entitled to an opportunity for decent homes just as they are entitled to an opportunity for education, and in the indisputable fact that high rates of sickness and death from preventable causes invariably prevail in substandard housing areas and that such areas are an economic and social blight to any community.

* Progress Report by the Joint Committee on Housing and Health of the American Public Health Association and the National Association of Housing Officials

2. Poor housing is almost always a concomitant of low economic status. Ill health is associated likewise with low economic status, both as a result of it and as a cause of it. People of small income may be found in good housing and people of fair income in slums, but this is so exceptional as to be something of an anomaly.

3. The fact that these social conditions, as well as personality factors, are complex and interrelated makes the isolation of a single factor, such as housing, beset with difficulties.

4. There is no single measurement of health. Mortality, sickness, physical examination findings, weight variations (especially in children), nutritional changes and nervous and mental disorders are possible measurements of health and may reflect definite reactions to environment as well as to other conditions. To measure health in terms of some of these indices is challenging—in the case of morbidity, for example, because it is not easy to define states of morbidity precisely. Most of the indices are, in fact, measurements not of health, but of the absence of health.

5. Different factors in poor housing may produce different effects. For instance, inadequate illumination may affect the eyes; room crowding may be related to the spread of communicable diseases; outside toilets may be a factor in the transmission of diarrheal disease through flies.

6. There is no need for surveys of the specific effects of housing simply to produce additional arguments for housing improvement. If it is not possible to establish specific effects on health, the case for good housing still will have ample foundation.

7. Studies of an entirely different nature from those here under discussion, are of great importance. Exploration of the physiological and psychological effects of certain factors in the design and construction of housing, such as has been done by the Committee on the Hygiene of Housing and other groups, produce valuable information on the specific factors in housing and health relationships. On many of these matters the known facts are still far from adequate. For these purposes, laboratory research is usually involved, and while such research is not contemplated in the type of study here under consideration, its value should not be overlooked.

PURPOSES OF THE REPORT

At present, little is known of the *specific* ways in which the provision of good housing may affect the health of families. If it is possible to determine

scientifically whether there are such specific effects and, if so, precisely what they are, it will constitute a worth while addition to our knowledge. As has been noted, most studies made for this purpose have not succeeded in establishing such effects because one or more factors of importance have been overlooked.

The Joint Committee has felt that it can perhaps be helpful by undertaking two things:

1. To point out some of the pitfalls in studies of this nature.

2. To endeavor to suggest techniques for a type or types of study that would evaluate in an acceptable manner the precise effects of the provision of good housing on health.

I. PITFALLS TO BE AVOIDED IN STUDYING HEALTH CONDITIONS AMONG WELL-HOUSED FAMILIES (THE EXPERIMENTAL GROUP) COMPARED WITH POORLY HOUSED FAMILIES (THE CONTROL GROUP) AS A MEASURE OF THE SPECIFIC EFFECTS OF THE PROVISION OF GOOD HOUSING ON HEALTH

The following pitfalls frequently observed in studies of this type are listed:

1. *Failure to start with a definite statement of purpose, setting forth the problem or problems to be explored*

Reason: In studies of the kind here under consideration, the purpose should be not to prove an assumption that there are specific, measurable effects, but rather to determine, if possible, *whether* there are such effects. A clear statement of objective is helpful in avoiding an effort to prove what we want to prove rather than to develop facts that need to be known.

2. *Comparison of disease prevalence or mortality rates among public housing tenants with such prevalence or rates among families in some selected bad housing area unless the methods used insure that the groups*

are comparable as to economic status, age groupings, family sizes, and the many other factors related to health

Reason: Differences in these respects may influence health more than housing does. For example, poverty itself has a known relationship to health; and both sickness and mortality occur at high rates among people in the older age brackets.

3. *Failure to consider the selective effect of tenant eligibility policies established for housing projects*

Reason: Such policies may bar families with poor health, poor credit and behavior records, with uncertain incomes, or because of other special considerations so that comparison with a group of poorly housed families is valid only when the two groups are comparable as to these factors.

4. *Failure, in making such a comparison, to consider the possibility of greater initiative on the part of applicants for housing projects, as a self-selective factor*

Reason: Families of low income that apply may be superior and in better health than those of comparable income that do not make the effort to get into such projects.

5. *Comparison of health factors among well housed and poorly housed groups without separate classification for occupation: and ethnic groups—whites, Negroes, Mexicans, etc.*

Reason: There are marked differences in morbidity and mortality rates among such groups.

6. *Use of mortality rates (except infant mortality and deaths from home accidents) covering a short period of time as a measure of health*

Reason: While mortality rates may be affected over a long period of time by differences in environment, they are not likely to be immediately affected by such differences.

7. *Use of morbidity data for diseases such as diphtheria or smallpox for which effective immunizing methods are available*

Reason: The extent of immunization rather than environment will be the important determinant as to the case rates from such diseases.

8. *Basing data on health department reports of diseases (such as pneumonia, enteritis, acute communicable diseases) that may be poorly or unevenly reported, if such reports are used to show improvement in the health status of a group of families over a period of years*

Reason: Data based upon incompletely and unevenly reported cases will in such instances be unreliable. If a control group is used, however, the degree of incompleteness should apply equally to both the experimental and the control group.

9. *Failure to consider comparability of special medical services available to both groups*

Reason: If housing project tenants have special advantages of this kind not available to the control group, any differences in health status might be due to these services rather than to housing.

10. *Using small groups without applying measures to rule out chance differences*

Reason: The numbers of persons involved may not be sufficient to provide statistically reliable results. Under proper conditions carefully selected small samples may be entirely reliable.

11. *Failure to select a large enough control group to allow for shrinkage in numbers over a period of time*

Reason: The size of the control group which it is possible to keep under surveillance throughout the study may decrease to the point that it is too small for valid comparison with the experimental group.

II. SUGGESTED TYPES OF STUDIES FOR EVALUATING THE SPECIFIC EFFECTS OF THE PROVISION OF GOOD HOUSING ON HEALTH

The committee has given much time to the study of valid techniques that might serve this purpose. It has sought also the advice and counsel of expert social researchers not members of the committee.

Many possible measuring devices have been considered. We are not yet prepared to recommend any that we are convinced will stand the test of searching analysis. The task is fully as difficult as we recognized it to be when we began our work. As one research specialist has stated: "There are few problems in the realm of social science more challenging than the one with which this committee is faced, and I suspect there are few problems in any science more difficult to solve." We shall not attempt to propose a method of evaluation until we are satisfied that it is adequate to the purpose.

The committee asks to be continued and respectfully requests officials of the American Public Health Association and of the National Association of Housing Officials to assist the committee to secure a research staff qualified to explore under our direction methods we have under consideration—and any others that may be suggested. This requires more detailed study than the committee's busy members are able to give. If this can be done, the time required for our task can, we believe, be materially shortened.

BCG

IT is commonly said that the progress of science knows no national boundaries; and such certainly ought to be the case. It is unfortunately not wholly true—as is evidenced in the history of BCG. It was in 1920 that Calmette and Guérin at the Pasteur Institute in Paris cultivated (by prolonged exposure to bile salts) a strain of tubercle bacilli which they considered non-virulent for man but capable of serving as an effective vaccine for the development of immunity against the disease. This discovery was hailed with enthusiasm in countries of Eastern Europe and South America, where French influence was strong; but for the most part ignored or opposed in Great Britain and the United States. It was fifteen years before any serious and impartial studies of the procedure were attempted in the Anglo-Saxon countries; and only today, after twenty-five years, have we fully appreciated the usefulness of BCG.

The first question to be settled with regard to a vaccine of this type is the possible danger that it may actually produce infection instead of developing immunity. Petroff at Saranac Lake showed that the "Bacillus-Calmette-Guérin" was actually a rough strain of the tubercle bacillus and that, in the laboratory, it could give rise again to the virulent smooth strain.¹ An episode at Lübeck in 1931 in which supposed BCG vaccination produced 72 deaths from tuberculosis among 251 infants treated² caused consternation. It was clearly shown however—and admitted by the laboratory worker who was responsible—that the Lübeck disaster was due to the fact that the BCG culture distributed had been contaminated with a normal virulent culture of the tubercle bacillus. The extensive use of BCG in France and Rumania and elsewhere without the slightest evidence of infection shows quite clearly that, whatever may be possible in the laboratory, BCG does not actually revert to a state of virulence in the human body. The *Journal of the A.M.A.* concludes "all reports agree that the vaccine properly prepared and used is harmless."³

The next question is "Does BCG actually protect against tuberculosis, and in

what degree?" The statistical evidence presented in the early French reports was extremely weak. Scepticism in accepting their results was fully justified; but such scepticism should have led to open-minded study, rather than to complete neglect of a procedure sufficiently promising to warrant impartial examination. W. H. Park was the only American investigator to exhibit interest and his results⁴ were distinctly promising, though not conclusive. A second later study from New York City has criticised the method of selecting control cases in the Park experiment, and has analyzed a second series of cases with what the authors consider better controls and has obtained results showing no protective effect.⁵

It was not until about 1935 that more extensive studies were made in Scandinavia and only during the last two years have really significant data been available for the North American Continent.

Experimental use on a considerable scale in Scandinavia offered promise at an early date, as shown by Wallgren in 1934.⁶

More recently, Hertzberg⁷ in Norway reported highly favorable results; and the National Society Against Tuberculosis now urges mass vaccination. Holm⁸ has recently given us a picture of striking experience in Denmark. Since 1940 intracutaneous vaccination with BCG has become routine in the Copenhagen tuberculosis clinics, and Holm reports that "tuberculosis morbidity and mortality among the children in the tuberculosis milieu have been reduced to almost nothing after systematic vaccination has been carried through." A special study among the medical students of the university showed 52 positive x-ray changes among 1,950 students with negative reaction to tuberculin; 17 positive x-rays among 1,950 students who had become tuberculin-positive through natural exposure; and no positive x-rays among 175 students who had been made tuberculin-positive by vaccination with BCG. A very striking study was made on the island of Bornholm where tuberculosis had been completely eradicated among cattle and where a positive tuberculin reaction among human beings was rare. During the period 1936-1940 the incidence of new human cases by age reached a peak at ages between 15 and 40. After an extensive program of BCG vaccination this peak almost disappeared, as shown by the following figures:

		Age → 15-20	21-25	26-30	35-40
New Cases	1936-1940	17	35	19	14
	1941-1945	8	7	12	6

Evidence of this sort has convinced leaders in this field in Great Britain that BCG should be made available for trial in that country⁹; and recently the important possibilities of this protective agent have been made clear in the United States and Canada.

Aronson and Palmer¹¹ have recently made a contribution of the first importance. They dealt with a group of young persons on an Indian Reservation (ages, 1-20 years) of whom about one-half (1,550) were immunized with BCG while 1,457 served as controls. Tuberculosis rates were normally high among these Indians, and the results after a six year period are most striking. Twenty-eight deaths from tuberculosis occurred in the control group and 4 in the immunized group. The death rates per 1,000 person-years were 3.3 in the control group and 0.5 in the immunized group; and the death rates from other causes 3.9 in the control group and 3.3 in the immunized group. Furthermore, analysis by successive years showed that (for a six year period) the difference between the two

groups increased progressively, so that there was no tendency, in that time, for immunity to wear off.

Still more recently Ferguson in Canada¹² has presented equally striking figures on protection of nurses by BCG. In eight Saskatchewan general hospitals, and in the Winnipeg General Hospital, and in three Saskatchewan tuberculosis sanatoria, groups of nurses and other employees negative to tuberculin were immunized with BCG and compared with control groups not so protected. The numbers were considerable (over 4,000 in all, of which about half were controls). The results were as follows, after an exposure time of 1-2 years (comparable in protected and control groups).

	Per cent Subjects Developing Tuberculosis		
	Positive Tuberculin	Negative Tuberculin	
		Immunized	Control
Saskatchewan General Hospital	1.1	0.9	3.8
Winnipeg General Hospital	1.0	0.9	4.0
Saskatchewan sanatoria	2.8	2.3	11.7

Thus, it appears that BCG immunization reduced tuberculosis incidence by 76-80 per cent, a rate comparable to that for the group which had acquired a tuberculin-positive state in natural ways.

These investigations seem to demonstrate beyond much doubt that BCG may reduce the incidence of tuberculosis to less than one-fourth the level which it would otherwise attain. It seems clear that its use for specially exposed groups such as nurses and sanatorium attendants; for groups with high incidence of the disease, such as the Indians; and in areas where clinic and nursing sanatoria facilities are inadequate should prove a primary instrument in the control of tuberculosis. Its rôle in a community amply provided with such facilities is not clear. Levine and Sackett⁵ believe that the routine vaccination of children in tuberculous homes is less advantageous than removal of the tuberculous source of infection from the home. An editorial in *Public Health Reports*¹³ calls attention to the uncertainty of the period for which immunity against tuberculosis may be maintained. On the other hand, the Danish authorities⁸ believe that the general use of BCG is warranted on the ground of the fact that the control of both bovine and human tuberculosis is rapidly building up a non-immune population and that it is important to build up an artificial herd-immunity to replace the immunity built up in the past by repeated small doses of infection.

The door is now open at least for the vigorous use of BCG immunization where it is desirable and for practical determination of the limits of that desirability.

PRINCIPLES OF A STATE "EQUALIZATION" PROGRAM

THE program of federal and state aid to local communities appears now to be well established as a part of governmental policy in the United States. It has been adopted in recognition that improvement of the health of the people is a vital function of government and that—since disease knows no political boundaries—it is essential to equalize opportunities for health in city and country, in well-to-do and in less prosperous areas. Federal as well as state grants for this purpose are, in general, channelled through the state departments of health; and it is essential that these departments should adopt clear and equitable policies for the distribution of such funds.

Uniformity between the states in making available grants-in-aid need not—and probably should not—be considered essential. Local differences exist which fully justify variations in procedure. Yet certain broad principles have been established by experience which are generally applicable and seem worthy of review.

In the first place, it seems obvious that the local community which receives state or federal aid should itself participate financially—and in substantial degree—to the support of its own local program. The philosophy of public health practice in the United States and Canada is based on the principle of local self-government. We assume that the health program is one for which the citizen feels individual responsibility and in which he will actively participate.

In the second place, it is generally—though not universally—believed that the participation of the state in a health equalization program should extend, in greater or less degree, to all areas within the state. Against this policy it is argued that only the more needy areas should receive any financial assistance. From the standpoint of equalization, this would perhaps be justifiable; but from a practical standpoint, it must be recognized that the greater part of the taxes comes from the wealthier jurisdictions, and the latter do not look with equanimity on having their money used for the aid of weaker financial areas to the exclusion of any benefit to themselves. It is for this reason that basic federal grants are made available for all states, and supplemented by special grants on grounds of need.

The provision of basic aid to all local jurisdictions in a state has been approached in two ways: (a) by a flat grant, as was instituted in Ohio some years ago and as has been proposed in South Carolina, and (b) by a grant to the locality of a certain percentage of the local health budget, as is provided under the present New York law.

In all cases, state aid should be contingent upon approval by the state health authority of the contemplated program, the budget and the personnel of the local health service. Frequently it may be desirable for the state regulations to include a requirement that local jurisdictions below a stated population must combine with other areas to make efficient health administration possible before receiving an allotment. It will generally be desirable to include a state legislative provision limiting grants to those areas organized under a full-time health officer.

If the principles discussed above are adopted, every area within the state, having provided for an essentially sound organizational framework, and prepared to provide substantial financial support for its program, would be eligible for state aid.

The first step in setting up an equalization program, under these assumptions,

is for the state health department to establish a minimum per capita cost for basic health service. This figure will vary with health needs and with the economic capacities, but for any given state it should be established as the minimum figure (including federal, state, and local funds) which will give sufficient grounds to believe that an effective health unit can be maintained. Except on a temporary emergency basis, grants-in-aid should not be made to a locality unless such an adequate budget can be reasonably visualized. The actual figure will vary from state to state and from time to time; but Emerson's \$1.00 per capita should be generally considered as a minimum.

The next step is the program for state grants as an equalization factor to bring the actual contribution which the local area can make, plus the basic state grant discussed above, up to the per capita cost which has been fixed as a normal minimum. The object here, of course, is to insure that no local jurisdiction (or combination of them) will remain in want of a satisfactory level of health service merely because it occupies an unfavorable financial position.

To insure this end it would seem necessary to establish a state-wide schedule or formula for state aid. Regardless of the basis used, such an equalization factor should contain a provision that when a local jurisdiction makes a financial contribution proportional to its wealth (on a basis previously determined for all local jurisdictions) to meet its public health budget, and if the amount thus produced, plus the basic state grant, fails to meet its health needs, then the state will provide the funds necessary to bring the local budget up to the previously determined per capita figure.

Before this supplementary aid is given, one state might require that each jurisdiction levy a specified tax for public health purposes; another state may elect to say that each local jurisdiction must set aside a certain percentage of its tax income. Still another possible arrangement is one whereby the part of the budget not provided by the basic state grant is provided jointly from state and local sources, the local jurisdiction participating financially in the same ratio that its per capita assessed valuation bears to the average (or median) per capita assessed valuation of the state as a whole. Under this latter scheme, of course, local jurisdictions whose per capita assessed valuation is equal to, or above, that of the state as a whole, receive no aid beyond the basic grants.

One of the great difficulties is to establish a schedule that is easily explainable to, and understandable by, local and state authorities. If one goes much further than "assessed valuation," the problem is likely to become complicated, though it must be confessed that, in some circumstances, assessed valuation is a manipulable element. One of the southern states uses community population as the key element in its equalization scheme. They find that in their circumstances there is correlation between population and wealth and, therefore, smaller towns and counties are given, by stated schedule, greater aid than larger ones. Population has the merit of being easily understood and probably has a more human appeal than valuations.

In addition to the basic grant and the additional grant based on economic need, some administrators believe that, in any scheme for state aid, a provision should be made under which special grants could be made to meet unusual health problems existing in particular areas. There are others who contend that, in general, special problems (at least within a state) occur pretty largely in the areas of low wealth and that equalization provision on an economic basis will meet "special problem" needs. It is obvious that the provision of grants on a "special

problem" basis involves the possibility of political pressures which may be difficult to meet.

We realize that such a program as that here outlined may seem Utopian. It is probable that for some time to come state grants in many states will continue to be made on a catch-as-catch-can basis, for a full-time health officer in one town, a nurse in another, a health educator in a third, a venereal disease clinic in a fourth—in accord with local demands. We believe, however, that the principles outlined are in fundamental accord with those which are to be followed in such states as Illinois, New York, and Washington and that general practice is likely to move in the future in the direction indicated.

STANDARDS FOR FROZEN FOODS?

TECHNOLOGICAL advances are constantly presenting new problems to the health administrator; and one such new problem is that of frozen foods. In any large community, there are now many stores handling products of this kind, and their number and variety are increasing year by year. In the past, frozen vegetables and meats were the chief products sold. Nowadays there are establishments providing complete cooked meals, ready to serve after placing them in the oven for ten minutes.

Are there possible new dangers involved in such procedures? We have no evidence that such is the case; and, in general, low temperatures are highly effective in checking bacterial development. If any hazard exists, we should expect that it might be due to rapid development of organisms present *after* the food has been thawed out. On general principles, however, any new situation of the kind will bear watching. As Dr. T. M. Drown of M.I.T. used to say about water supplies "the time of change is the time of danger."

Should we have special laboratory standards for the control of products of this kind? The head of one of our largest city laboratories reports that no such standards are available, and that the Federal Food and Drug Administration has no information on the subject.

It may be well that present sanitary regulations in regard to food handling and food handlers are entirely adequate and that no new hazards are involved in the problem of frozen foods as such. It would be well, however, for epidemiologists to be alert with regard to any disease possibility associated with such products; and it might be desirable for our larger laboratories to initiate preliminary research on the bacteriology of frozen food products.

THE CRISIS IN EDUCATION

The National Education Association of the United States, Washington, D. C., packs a big wallop with the 16 pages of the annual report of the profession to the public entitled, "Our Children." Contrasting the citizens we need in a jet-propulsion age with the kind of citizen we have, analyzing the reasons for the vanishing teacher as underprivileged economic and social status and professional insecurity, it suggests that not less than 5 per cent of national income should be spent on public schools. There are charts showing that in 11 states one-fifth or more of adults over 25 years had completed four years or less of school, that enrollment in teachers' colleges has decreased from about 170,000 in 1940 to less than 70,000 in 1946, while emergency certificates have increased from 5,000 to 110,000 in the same period. For the skeptic who still thinks public education is a bit of a luxury, it points out that 31 of the 48 states hold the same relative position among the other states in the amount of retail sales per capita which they hold in relative educational levels of their population. Conclusion: "Schooling pays. We can afford to educate our children."

Perhaps the Amen corner will say "And we can afford to give all our people basic health protection."

EDUCATION IN HANSEN'S DISEASE

The National Leprosarium in Carville, La., dates back to 1894 when it was opened for 8 patients by the State of Louisiana. In 1900 new buildings on another site were burned down by neighbors strongly opposed to such a hospital in their neighborhood. Hence the original site, the old Indian Camp

Plantation, was continued with the addition of suitable cottages and hospital. By February, 1931, after a long period of negotiation, title of the Louisiana home was transferred to the U. S. Public Health Service under whose jurisdiction it has since been operated. At present there are modern fireproof buildings for 480 ambulatory patients and 65 hospital rooms for bed patients on a 350 acre tract of land. It is a self-sustaining community with its own power plant, water supply, sewage disposal, dairy, farms, etc. Among the activities of the patients is the monthly publication, *The Star*, whose masthead carries the words, "Radiating the Light of Truth on Hansen's Disease." Among its chief aims is to reëducate the public with respect to leprosy (they prefer to call it Hansen's Disease) and root out many of the misconceptions about it that go back to Biblical times.

A recent issue of *The Star* quotes F. C. Lendrum, M.D., Assistant Professor of Medicine of the University of Illinois College of Medicine, to the effect that "At the present time a person who is branded as a leper suffers more from the word than from the disease. Leprosy is certainly the least communicable of all communicable diseases. It could be treated in general hospitals with vastly more safety than can tuberculosis. The public health problem at present is less that of discovering new drugs for the treatment of leprosy than that of persuading patients stigmatized as lepers to submit to treatment."

As a contribution to the education of the public in a proper perspective, *The Star* of July, 1946, reproduces, prior to publication, the chapter on Hansen's Disease in *Opportunities for Service to Mankind*, by Col. C. H. Rarey, U.S.A.

Ret. Here is given the history of the disease and the isolation of the *Bacillus leprae* by the Norwegian Hansen in 1874. He outlines five current needs with respect to the problem and makes suggestions for citizen service in connection with each. The five are:

a. Research into the cause of and method of transmitting leprosy. This is the chief activity of the Leonard Wood Memorial (American Leprosy Foundation).

b. Need for reëducating the American public upon the subject of leprosy. Among facts mentioned here are that, in the 52 years of the National Leprosarium's existence, not a single member of the medical or nursing staffs has contracted the disease.

c. Reconsidering and changing the present segregation policy. This policy defeats its own purpose because it prevents many sufferers from coming under treatment. If they were hospitalized rather than banished many would be returned to lives of usefulness.

d. Rehabilitation of patients at the National Leprosarium, particularly through an extension of the occupational therapy program.

e. Moving the Leprosarium activities to a cooler, dryer climate.

Further timeliness of this problem is indicated by news from the Advisory Committee on Leprosy to the U. S. Public Health Service. Meeting in Washington in December, this committee, made up of a distinguished group of leprologists and interested citizens, recommended to the Surgeon General an approach to the problem from the viewpoint of public health rather than the present segregation and institutional care. Emphasis should be upon case finding, outpatient treatment, periodic reëxamination of discharged patients, and a program of education for diseased persons, their families, and the public. This program should be carried on with the collaboration of state and local health departments and medical schools with the main effort in endemic areas—California, Florida, Louisiana, and Texas. Each of these states should have a special treatment center to replace the present Leprosarium.

While these basic long-range recom-

mendations are being put into effect this Advisory Committee recommended minor changes in existing policies at the Leprosarium—extended leave privileges, appointment of medical-social workers to the staff, extension of occupational and physical therapy, increased recreational facilities, codification and publication of existing regulations, and an intensive educational program for patient, family, and general public.

CREDIT WHERE CREDIT IS DUE

Dr. James E. Perkins, Chairman of the Committee for the Evaluation of Methods to Control Air-borne Infections has asked the JOURNAL to call attention to the fact that the report entitled "The Present Status of the Control of Air-borne Infections," appearing in the January JOURNAL was prepared by Dr. Alexander Langmuir, Associate Professor of Epidemiology, the Johns Hopkins University School of Hygiene and Public Health, Baltimore.

AN INVESTMENT IN PERSONNEL ADMINISTRATION

EDITOR'S NOTE: The report of Charles B. Frasher, Field Consultant of the Merit System Unit, American Public Health Association, on a visit to a small mid-western city is abstracted here for the interest of health officers, particularly those with relatively small staffs.

The health officer of a small mid-west city was the first local health officer to request field consultation services which were made available by the American Public Health Association following a grant-in-aid by the National Foundation for Infantile Paralysis, Inc. A visit of four days was made at his request to set up a "merit system."

The health officer explained that he did not know much about a merit system of personnel administration but wanted to take advantage of the good principles inherent in such a system.

It was decided that the first and most important job would be the classification of positions in the department. Twenty-nine employees required about 29 separate class descriptions or specifications due to the complexity of the work. Believing it would produce greater acceptance of the plan if the director of each service had a part in working out a classification plan, the health officer, the director of each service, and the consultant wrote the job description for each director and, in some cases, for one or two subordinate positions. The director was then given the task of developing the other job descriptions in his unit. The job descriptions in the classification plan, being a statement of the facts about positions for the guidance of employment officers and employees, were written according to the following outline:

1. *A title*—descriptive of the position
2. *A definition*—a brief description of the duties
3. *Examples of work performed*—giving in considerable detail the duties of a group of similar positions
4. *Minimum qualifications*—including the education and experience and the knowledge and abilities which are the minimum necessary for the successful performance of the duties of the position

A statement including the above is called a *job description* or a *class specification* of a *class of positions*. In any well written plan there is also a *range of classes*, a series of positions increasing in responsibility and experience required, whereby an employee can see that by the acquisition of additional qualifications he can advance to more responsible duties. These are now complete and are being reviewed by subject-matter consultants on the Merit System Unit staff.

The next step was to develop a compensation plan which, since the city council was considering "cost-of-living" increases, was developed separately from the classification plan. The ad-

ministrative staff met to consider salaries for all the classes of positions in the classification plan. A number of local conditions had to be considered—available finances, services to the city, comparable wages in industry and business. The fact that the city fathers recognized the importance of public health by making the health officer the highest paid city official, made the task easier. A compensation plan, evolved after discussion, provided for:

1. A minimum entering wage
2. Periodic increases for satisfactory work
3. Maximum wage

The group would not, at this time, approve a proposal to provide for additional increases for satisfactory service after a period of service at the maximum wage.

The next task was to write some operating rules and regulations relating to personnel management. The state health department has a well written set of rules and regulations for operating a merit system of personnel administration. A copy of these was secured and a set of rules, patterned after the state's rules, was developed. This was important in view of the probability of using some of the services of the state at a later date. The rules, as finally written, included such details as the responsibilities of the health officer and the advisory health council, the methods of selecting personnel and determining eligibility for employment, methods for promoting, demoting or releasing persons from employment, sick and vacation leave policies, and the like. A retirement plan was proposed and the health department officials will investigate some plans.

The problem of using examinations for selecting persons was next discussed. There was no local examining authority in the city other than a branch office of the U. S. Civil Service Assembly. The health officer decided that he did

not want to make a final determination at this time. It was therefore suggested that the health officer call his system "personnel administration" or "personnel management" rather than to use the term "merit system," for the latter includes equal opportunities for everyone to become eligible for employment. At a later date the health officer will adopt this latter principle of selection by competition or by merit.

This experience of working with a local health officer and his staff in preparing a classification plan, compensation plan, and operating personnel management rules was a most enjoyable one and it was the consensus that health work will be improved by the fact that properly qualified persons will be secured for the important public health tasks, and by the fact that employees will know their rights and privileges.

The group agreed that too much mystery surrounds the magic words "merit system." When broken down into its component parts, it is simply an agreed-upon system of providing qualified workers for duties and of assuring them of good working conditions and freedom to work within the limits of their capabilities. The health officer has asked for a return visit within a year to work further on the plans and procedures.

AIDS TO DISCUSSION OF NATIONAL HEALTH INSURANCE

"Platform" is a special bulletin of the *Newsweek Magazine* prepared for women's clubs in all parts of the country. The December, 1946, issue has an outline of the pros and cons of National Health Insurance suitable for club discussions of the subject. In preparing the bulletin *Newsweek* had the assistance of the Committee for the Nation's Health, which is quoted at length in the bulletin. Available without charge from Newsweek Club

Bureau, 125 W. 42nd Street, New York 18.

RADIO CANCER FORUM

The Nassau County (N. Y.) Cancer Committee broadcast a Public Cancer Forum recently as a part of its Ninth Annual Cancer Institute. This was a sponsored program without advance knowledge of the panel speakers' texts by either sponsor or station. Questions from both the visible and radio audience were answered by the panel representing specialists in cancer of the breast, female genital organs, digestive tract, head and neck. It is reported that the public reaction has been uniformly enthusiastic, with an unmistakable preference for this audience participation type of program over the traditionally didactic cancer lecture.

COMMITTEE FOR KENTUCKY

"The Committee for Kentucky" is a fact-finding organization that has as its only objective the welfare of all of Kentucky. This committee has been publishing a series of reports the third of which is on health. Written by the state health officer, Philip E. Blackerby, M.D., it is a simple and highly effective stocktaking of Kentucky's health service with no slurring over of the unmet needs. Its first item for example is "Kentucky has the third highest tuberculosis death rate in the nation." The Plan of Action, proposed by O. O. Miller, M.D., Immediate Past President of the Kentucky State Medical Association, outlines the several immediate steps that need to be taken with regard to each of 13 problems—tuberculosis, sanitation, dental health, and others. For public health organization there is just one suggestion—"establish full-time health units in every county and provide for their adequate financial support."

It is an effective piece of public health education with bright and colorful

charts simply drawn. The entire series should do much to change the sociological map of Kentucky.

AMERICAN STANDARDS FOR 1947

The American Standards Association announces the publication of the 1947 edition of *American Standards*, dated January, 1947. Listed are 864 standards approved for national use by industry. Included in the standards are definitions of technical terms, specifications for metals and other materials, methods of work and methods of test for finished products. "They reach into every important engineering field. They also include standards dealing with public and industrial safety, industrial medicine, and a wide variety of consumer goods." Copies can be obtained from the American Standards Association, 70 East 45th St., New York 17, N. Y.

MINNESOTA'S NEW HEALTH DEPARTMENT BULLETIN

January saw the launching of *Minnesota's Health*, a monthly news bulletin of the Minnesota State Department of Health. This first issue tells of the streamlining of the state's health department through a reorganization into five sections to replace the nine divisions under which it previously operated. Section chiefs are as follows:

Departmental Administration: R. N. Barr, M.D., M.P.H.

Preventable Diseases: D. S. Fleming, M.D., M.P.H.

Medical Laboratories: Paul Kabler, M.D., M.P.H.

Environmental Sanitation: Herbert M. Bosch, M.P.H.

Special Services: Viktor O. Wilson, M.D., M.P.H.

The same issue tells also of the organization of the Minnesota Committee on Local Health Service under the chairmanship of William B. Pearson, Master of the State Grange of Minnesota. This committee, widely repre-

sentative of professional and citizen groups, has drafted a permissive health unit bill which "if enacted, will make possible the establishment of local health services and the employment of full-time health officers and other necessary personnel by all Minnesota communities that want them."

Congratulations to the new bulletin and its editor, Netta W. Wilson of the Minnesota Health Department's Public Health Education Unit.

ODORS—AND ODORS

The Hospital Bureau of Standards and Supplies (247 Park Avenue, New York 17) throws a salutary dash of cold water on the magic compounds that will give air "country air freshness." In a recently published pamphlet, *The Problem of Odors in Institutions*, by Dewey H. Palmer, it declares that good ventilation and frequent cleaning are still the best solution of the odor problem, that the widely sold deodorizers merely substitute one odor for another.

Activated carbon is the only generally available substance that can adsorb odors in large quantities. There are two present methods based on the use of activated carbon adaptable against odors from putrefaction. One is a mechanical device, the other is a medicated filter cloth.

GREENWICH STARTS A HEALTH BULLETIN

In October, 1946, there appeared Vol 1, No. 1 of the *Greenwich Health Bulletin*, published by the Greenwich (Conn.) Tuberculosis and Health Association. Designed as a quarterly, its first issue gives this reason for its existence: "In our community there seems to be no lack of private and public services which directly and indirectly safeguard our health. The greatest need appears to be better knowledge and appreciation of all services available."

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted. All books reviewed in these columns may be purchased through the Book Service.

Dentistry: An Agency of Health Service—By *Malcolm Wallace Carr*. New York: *The Commonwealth Fund*, 1946. 219 pp. Price, \$1.50.

Dentistry is one in a series of monographs issued under the auspices of the Committee on Medicine and the Changing Order of the New York Academy of Medicine.

Writing for the intelligent layman, Malcolm Carr and a group of prominent contributors describe the history of the dental profession, dental education, dental practice, research, and dental socio-economics. Summary and conclusions representing the thinking of dental authorities will merit the consideration of public health leaders. "The autonomous dental profession," says the author, "has acquired special competence in the related sciences and arts of dental health care." The author then adds that "a recent survey has indicated that medical faculties are inattentive to the principles of oral pathology related to systemic diseases and to the clinical aspects of the diseases of the mouth."

It is surprising how much data and how much authentic information concerning dental health have been included in the comparatively few pages of this volume.

In describing the status of organized dentistry, the author urges the dentist of tomorrow to have "a broader scientific and public health background." Your reviewer goes a step further by suggesting that public health personnel obtain a broader and more comprehensive background of dental

health as it is related to public health.

Admittedly one book, even one so well written as is *Dentistry*, will not of itself bring about the desired changes in the thinking of dentists and public health administrators. Nevertheless its wide reading in both professions should enhance the social utility of the dental profession.

J. M. WISAN

Insect Microbiology—By *Edward A. Steinhaus*. Ithaca, N. Y.: *Comstock Publishing Company*, 1946. 763 pp. Price, \$7.75.

The extremely varied associations between insects and microorganisms (including viruses) are grouped by Dr. Steinhaus in ten categories, each of which forms a separate chapter. On account of the closely similar conditions seen in ticks, especially in their activity as vectors of disease, these other arthropods are included.

The first two chapters deal with extracellular bacteria and specific bacteria associated with insects, including many references to species pathogenic to insects, as well as human pathogens that occur sporadically in insects or on their bodies. An account of the remarkable bacterium-like and rickettsia-like symbiotic organisms which occur intracellularly in diverse insects forms the fourth chapter. Following this is an extensive treatment of the rickettsias of ticks and insects. This includes much material on the difficult and complex problems presented by the rickettsial diseases of man. A chapter on yeasts is devoted mainly to a consideration of the yeast-like symbionts that oc-

cur chiefly in the sap-sucking insects of the order Homoptera. Following this the much more diverse relations of insects with fungi are discussed, including parasitic forms, those serving as food for insects and those fungous parasites of plants which are disseminated by insects. A chapter on viruses deals mainly with those causing diseases in insects and with those concerned in diseases of other animals and plants which are spread by insect vectors. Two chapters relate to Protozoa, one dealing entirely with the peculiar symbiotic flagellates of termites. Finally there is a chapter on immunity, a long and very well selected bibliography of nearly 90 pages, and a complete index.

Dr. Steinhaus has presented a vast amount of material not hitherto available in correlated form, which will be highly useful to a wide audience of entomologists and biologists in general, including pathologists, human and otherwise.

CHARLES F. BRUES

Manual of Applied Nutrition—
Compiled by H. Baughman, K. M. Lewis, and E. R. Trescher (rev. ed.). Baltimore: The Johns Hopkins Hospital, 1946. 103 pp.

This is a technical manual describing routine dietary procedures in The Johns Hopkins Hospital. It was compiled for the use of medical, nursing, and dietary staffs of the hospital. The first edition was published in 1940 and has been recently revised by representatives of several clinical departments and the nutrition committee of the hospital.

A comprehensive group of therapeutic diet plans have been included in this manual. Each outlines the approximate composition of the diet and a one day pattern meal plan. Normal dietary needs are briefly outlined and have been used as a basis for planning all therapeutic diets. Also included are diets during pregnancy and lactation.

infant feeding regimes, and normal diets for children of various ages. The diets for children are well adapted to hospital procedure but would require more flexible interpretation for the child at home. This reviewer feels that the emotional factors as a component of diet therapy have not been given sufficient emphasis.

The committees revising the manual say, "We have attempted to describe the routine dietary procedures as they are practised in this institution and to show that so-called special diets are usually simple modifications of the normal diet. It has been our purpose to present the necessary material in as brief a fashion as is consistent with clarity. In view of this, we have not permitted ourselves to indulge in discussion. It is hoped that many will be stimulated to review for themselves the basic facts of physiology, pathology and nutrition which have been given consideration in the compilation of this material."

This is in the true sense of the word a manual and would seem to be of limited value to public health workers not directly associated with this hospital. The manual would be useful, however, as a reference for the clinical and dietary staff members of other hospitals.

ANSTA TODD BARR

Personnel Policies for Public Health Nursing Agencies—
Prepared by the Committee on Personnel Policies of the National Organization for Public Health Nursing, 1946. New York: N.O.P.H.N., 1946. 31 pp. Price, \$.75.

This Guide on personnel policies for public health nursing agencies contains 31 pages, compiled in loose-leaf form so that pages may be replaced as changes are indicated, and individual agencies may insert copies of their own policies and other related materials. The recommended policies are clearly and concisely stated and were determined

on the basis of current and practical standards in personnel practice. They cover time, salaries, transportation, health program, staff development, staff council, uniforms, retirement plans, termination of services, and student program; also general principles and methods to be considered in establishing personnel policies.

The Guide points clearly to the need for defining personnel policies and should prove helpful to all agencies employing public health nurses. While much of the material will apply only to the nursing staff, the basic principles are applicable to personnel policies for all workers in public health agencies.

HELENE B. BUKER

The Day Care of Little Children in a Big City—*By Leona Baumgartner, M.D., et al., and Daytime Care—A Partnership of Three Professions—New York: Child Welfare League of America, Inc., 1946. Price, \$.50 and \$.35.*

It is to be hoped that the experiment described by the first of these pamphlets will not long remain unique. For while the day care problem in New York City is on a scale unapproached elsewhere, the nature of the difficulties of providing for children whose mothers are working outside their homes is much the same in all large cities. Many cities must, as a result of their immensely increased load during the war, be in process of reviewing the situation thus brought sharply to their attention.

It had long been recognized in New York that three public departments had a stake in day nurseries: the Health Department, the Department of Education, and that of Social Welfare. But only the Health Department had legal authority behind it, and what authority it did possess applied only to sanitation, building standards, fire hazards, and disease prevention.

Only after a survey in 1942 of the

city's facilities brought to light that close to 500 agencies were giving day care to children under 6 did things begin to move. Experts from all the fields concerned, called together by the Director of the Bureau of Child Hygiene, framed and proposed recommendations greatly broadening the scope of inspection standards. Evaluation was proposed in terms of the *total* care given the children. In other words, mental health took its proper place alongside physical health; and a coordinated plan for putting to work the findings about what is necessary to the best growth and development of children came into being.

This plan, as finally worked out, set up a Day Care Unit in the Health Department's Bureau of Child Hygiene. The move was the result of consultation among a widely representative group of interested organizations, such as the Welfare Council and The Mayor's Committee on the Wartime Care of Children.

Both public and private help were provided, resulting in a staff of 6 professional workers (the director from the nursery education field), later increased to 9. With additional help from the State Departments of Social Welfare and Education, and from professionally trained volunteers, every day care center was inspected, advised and, in cases where it was necessary, either closed or given help in reaching higher standards. That in the second year of operation 47 centers closed, as against 70 the first year, suggests that fewer ill-prepared persons and organizations were attempting to undertake day care; a testimonial to the careful interviewing of prospective licensees. Only two court actions were necessary, to close undesirable places, but these undoubtedly had the effect of motivating efforts to bring others up to standard.

At least 50 per cent of the children receiving day care are in centers oper-

ated for profit, only one of the many reasons why it will be necessary for the day care unit to continue functioning.

In order to give children the care they are entitled to—far above the old concept of custodial care—only a team of experts, pooling their knowledge about children's needs—emotional, social and physical—and constantly striking out for new gains, can do the job. Supervision at the present time is far below what those with children's interests at heart would like to have it be. Among the far-reaching possibilities that have had to be left untouched, up to now, is the development of methods of working with the parents of these thousands of young children.

The second pamphlet, *Daytime Care*, is the outcome of a tri-professional conference on day care held by the Child Welfare League in 1945. Into it is packed the result of such soundly coordinated effort that it should be widely used in schools of nursing, public health, pediatrics, social work, and nursery education. It would be invaluable as a means of implementing any such effort as that described in the first pamphlet. KATHERINE BAIN

Manual of Recommended Practice for Sanitary Control of the Shellfish Industry—Public Health Bulletin No. 295. Washington: U. S. Govt. Ptg. Office, 1946. 44 pp. Price, \$.15.

This *Bulletin* was prepared by the U. S. Public Health Service as a guide to the shellfish industry and regulatory agencies responsible for shellfish sanitation, and represents the experience of the Service during twenty years of this work.

The *Bulletin* is very carefully indexed, includes useful definitions, and covers every phase of shellfish sanitation from the problems of growing areas, harvesting and handling, expressing and interpreting of laboratory results, details of construction, opera-

tion, and maintenance of shucking, packing, and shipping plants.

Each subject is divided into three main headings—(1) a statement of the recommendation or requirement, (2) the public health reason for the requirement, and (3) a statement of what constitutes satisfactory compliance with the requirement.

This *Manual* will be found extremely valuable and helpful to both the industry and those engaged in regulating the industry. It should provide a medium for a more uniform practice in shellfish sanitation than was possible previously.

M. H. BIDWELL

Proceedings and Papers of the Fourteenth Annual Conference of the California Mosquito Control Association—Edited by Harold Farnsworth Gray. Berkeley, Calif.: Issued by the Association, 1946. 115 pp. (mimeo.). Price, \$1.50.

These proceedings include 19 papers dealing with various phases of mosquito control, presented chiefly by workers in this field in California. Over half of the papers discuss the use of DDT, methods for its distribution by both ground and air apparatus, its toxicity to harmful and beneficial insects, its effect upon fish and wildlife generally, and its hazards to man.

The California state program for control of mosquito-borne diseases is described. Special emphasis is to be placed on gathering information on the distribution and biology of mosquitoes known to be vectors of encephalitis and malaria. Under a Bill pending in the Legislature, the Department of Health is authorized to coöperate with local mosquito abatement districts in furthering mosquito control. Financial assistance not to exceed 50 per cent of the total cost of any acceptable plan may be provided by the department on behalf of the state. The Bill calls for an appropriation of \$600,000.

Reports of accomplishments by mosquito abatement districts are given, together with discussions of problems encountered during the year.

The proceedings contain a wealth of current information of value and interest to public health workers engaged in mosquito and other insect control work.

GEORGE H. BRADLEY

The Health Instruction Yearbook, 1946—Compiled by Oliver E. Byrd, Ed.D. Stanford, Calif.: Stanford University Press, 1946. 399 pp. Price, \$3.00.

Three times in the last two volumes of our *Journal*, the annual editions of this *Health Instruction Yearbook* have been praised by reviewers. The first concluded judiciously, "As a source book, this volume . . . should find a place in every health educator's library." The second began, exuberantly, "Here it is! A book . . . every health officer . . . should add to his, or her, group of essential personal desk references." (The last dots represent varieties of health workers too numerous to list here.) The third reviewer, purse-mouthed, sums up the 1945 edition, "The *Yearbook* seeks to keep abreast the rapidly changing developments and problems in public health, medicine, and allied areas, and succeeds very well indeed."

Now the fourth edition claims your patronage through our Association's Book Service. Instead of piling another Ossa of eulogy upon this Pelion of praise, it seems more profitable to try to tell you just what this hardy perennial is. But, first, what it isn't! It isn't a handy reference volume of the health literature of 1946. It couldn't possibly attempt the task. A book the size of Webster, unabridged, couldn't hold it all.

In the *Yearbook*, the author summarizes the advances in public health as reported between the first of September of the preceding year and the last of

August of the current year of review. To do this he abstracts (in the 1946 edition) 384 articles from 83 different sources. He groups the items in 21 categories, beginning with social accomplishment and social problems, through the usual hygienic rubrics—nutrition, infectious and chronic diseases, safety and the like—ending with community services, trends, and (new) international health.

At the beginning of each category he epitomizes the abstracts to be grouped there. Each item has, of course, a reference to the source and each is written in readable English—not abstractese!

The author accomplishes what he sets out to do. He presents a comprehensive, orderly picture of what has been going on in the (health) world. If you want to relate your work and your self with the moving tide of affairs, then reading this *Yearbook* will be a rewarding—and a pleasant—experience.

RAYMOND S. PATTERSON

American Foundations for Social Welfare—By Shelby M. Harrison and F. Emerson Andrews. New York: Russell Sage Foundation, 1946. 249 pp. Price, \$2.00.

Students of public health will do well to note this new volume descriptive of American foundations and sure to be helpful to those who want to make contacts with such agencies for any purpose.

The heart of the volume is a directory of 505 foundations. Chapters on financial aspects, fields of activity, trends and possible developments round out the story. Taken together with the publication of the Raymond Rich Associates in 1942—*American Foundations and Their Fields*, 5th edition, we now have available adequate studies of American foundations.

According to this report, one hundred and twenty-nine foundations, or

38.5 per cent, indicate that health is a major concern, forty foundations regard health—or one of its sub-heads such as mental hygiene and the care of the handicapped—as the sole major interest. Foundation interest in health is exceeded in this survey by interest in the fields of education and “social welfare.”

The latter term, however, is recognized as a catch-all.

A reader of this work will wonder whether society will long tolerate the tax-free foundation which refuses to divulge the manner in which it spends its funds.

REGINALD M. ATWATER

BOOKS RECEIVED

Listing in this column acknowledges the receipt of books and our appreciation to the senders. Space and the interests of readers will permit review of some, but not all, of the books listed.

ACCIDENT PREVENTION MANUAL FOR INDUSTRIAL OPERATIONS—National Safety Council. Chicago: National Safety Council, 1946. 534 pp. Price, \$14.00 (\$7 to members of National Safety Council).

ADJUSTMENT TO PHYSICAL HANDICAP AND ILLNESS: A SURVEY OF THE SOCIAL PSYCHOLOGY OF PHYSIQUE AND DISABILITY—By Roger G. Barker, Beatrice A. Wright and Mollie R. Gonick. New York: Social Science Research Council, 1947. 372 pp.

ANNUAL REPORT OF THE DIVISION OF LABORATORIES AND RESEARCH. By Gilbert Dall-dorf, M.D. Albany: New York State Department of Health, 1945. 111 pp.

BABY—A MOTHER'S MANUAL. By Stella B. Appelbaum. Chicago: Ziff-Davis, 1946. 118 pp. Price, \$2.50.

BOVINE MASTITIS—A Symposium. Edited by Ralph B. Little and Wayne N. Plasteridge. New York: McGraw-Hill, 1946. 546 pp. Price, \$7.00.

BEAUTY PLUS. By Mary MacFadyen, M.D. New York: Emerson Books, Inc., 1947. 272 pp. Price, \$2.49.

THE COMPLETE PEDIATRICIAN. By Wilburt C. Davison, M.D. (5th ed.) Charlotte, N. C.: Duke University Press, 1946. 256 numbered items. Price, \$3.75.

THE CULTIVATION OF VIRUSES AND RICKETTSIAE IN THE CHICK EMBRYO. By W. I. B. Beveridge and F. M. Burnet. London: His Majesty's Stationery Office, 1946. 92 pp. Price, \$6.00.

DANIEL COIT GILMAN. By Abraham Flexner. New York: Harcourt, Brace & Company, 1946. 173 pp. Price, \$2.00.

DIRECTORY OF BIOLOGICAL LABORATORIES WITH BUYERS' GUIDE. Chicago: Burns Compiling and Research Organization, 1946. 120 pp. Price, \$3.00.

EMPLOYMENT, REHABILITATION AND VETERAN ADJUSTMENT—A Bibliography, 1940-1945. By Paul S. Burnham. Chicago: Public Administration Service, 1946. 27 pp. Price, \$1.00.

ESSENTIALS OF PHYSIOLOGICAL CHEMISTRY. By Arthur K. Anderson. (3rd ed.) New York: Wiley, 1947. 395 pp. Price, \$3.50.

FACTS ABOUT NURSING. Nursing Information Bureau. New York: Nursing Information Bureau, 1946. 112 pp. Price, \$35.

FOOD AND HEALTH. By Henry C. Sherman. New York: Macmillan, 1947. 290 pp. Price, \$4.00.

FUNDAMENTALS OF SEMI-MICRO QUALITATIVE ANALYSIS. By Carl J. Engelder. New York: Wiley, 1947. 385 pp. Price, \$3.50.

GUARDING YOUR HEALTH IN 1946. By Arthur L. Ringle, M.D. Seattle: Washington State Department of Health. 28 pp.

GROUND WATER IN THE BALTIMORE INDUSTRIAL AREA. By John C. Geyer. Baltimore: Maryland State Planning Commission, 1945. 299 pp. Price, \$1.00.

HEALTH AND BODY BUILDING. By Frank Merrill Wheat and Elizabeth T. Fitzpatrick. New York: American Book Company, 1947. 517 pp. Price, \$2.08.

HOSPITAL RESOURCES AND NEEDS. The Report of the Michigan Hospital Survey. Battle Creek, Michigan: W. K. Kellogg Foundation, 1946. 172 pp.

HOW TO LIVE. By Irving Fisher and Haven Emerson. (21st ed.) New York: Funk & Wagnalls, 1946. 354 pp. Price, \$2.50.

HOW TO OBSERVE PUBLIC HEALTH NURSING WEEK APRIL 20-26, 1947 IN YOUR COMMUNITY. National Organization for Public Health Nursing. New York: N.O.P.H.N., 1947. Price, \$.50.

- IMPROVISED EQUIPMENT IN THE HOME CARE OF THE SICK (4th ed.). By Lyla M. Olson. Philadelphia: W. B. Saunders, 1946. 265 pp.

- YOUR RHEUMATISM AND BACKACHES. By Joseph D. Wassersug, M.D. New York: Wilfred Funk, Inc., 1947. 310 pp. Price, \$2.50.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Gay Hymeneal Note—Combined here are the first and last sentences of an interesting statistical summary. "Marriages in the United States reached an all-time high in 1946 . . . it does not appear likely that the marriage record established will be reached again for many years to come." The cause seems to be, mostly, delayed "intin-tions," as we say in Boston.

ANON. 1946—A Peak Year for Marriages. Stat. Bull. (Met. Life Ins. Co.). 27, 12:1 (Dec.), 1946.

Canadian Inspector Speaks Out—Privileged heads roll right and left in this chief inspector's uninhibited plea to health workers generally to take an active part in demanding a Federally subsidized housing program to provide decent dwellings for low income groups. Is it possible that the housing situation this side of the border calls for some out-speaking, too, on our part?

AUSTIN, F. C. The Real Housing Problem. Canad. Pub. Health J. 37, 12:488 (Dec.), 1946.

Research, Training and Community Services—More than eight million Americans endure some form of mental illness and 600,000 of them are now in mental hospitals. Health officers join with the psychiatrists to see what can be done about this poser. Whatever your job, this is something you, too, should be concerned about.

FELIX, R. H. The Relation of the National Mental Health Act to State Health Authorities. Pub. Health Rep. 62, 2:41 (Jan. 10), 1947.

Therapeutic Pitfalls: Public Health Hazards—Though these sound warnings about the limitations of

penicillin therapy of syphilis are mostly medicine, certain public health aspects of the problem are not neglected. The returned veteran, the question of marriage, the dangers of hidden infections, among others, are discussed and these are of moment to you.

HILL, W. R. Problems Arising in the Treatment of Syphilis with Penicillin. New England J. Med. 235, 26:919 (Dec. 26), 1946.

Preliminary Report—You should know about some forms worked out to facilitate notification of venereal disease contacts and sources of infection. They proved acceptable to practising physicians who had formerly been reluctant to collaborate, and despite obvious weaknesses, seem to work.

HOLLISTER, W. G. Self-Interview Forms in Private Physician Contact Reporting—A New Technic in Case Finding. J. Ven. Dis. Inform. 27, 10:240 (Oct.), 1946.

"Report Immediately"—Let the Western Union messenger be your case chaser-upper! That's the suggestion of this paper in which the claim is made that he is effective and economical.

KOCH, R. A., and THORNTON, M. Use of Telegrams in Venereal Disease Case Holding. J. Ven. Dis. Inform. 27, 10:246 (Oct.), 1946.

More about DDT—Three papers add to your knowledge of DDT. Blown into rat harborages and runways, DDT rids rats of fleas. Sprayed on building interiors it tends to discourage anophe-line mosquitoes from entering and biting after they enter. It also proves a useful laticide for anophelines.

LUDWIG, R. G., and NICHOLSON, H. P. The Control of Rat Ectoparasites with DDT (and two other papers). Pub. Health Rep. 62, 3:77 (Jan. 17), 1947.

Tip to Historians — All proper treatises on public health begin "at the beginning" with Edwin Chadwick, Father of Sanitation. If we are to believe this paper, the beginnings began before Chadwick, for Sir Thomas More (1478-1535) in his *Utopia*, provided a blue print for community health administration. In addition to his flights of literacy fancy, he was appointed by the king to work out some down-to-earth health measures to control the ever present plagues of his day. Codified, these orders survived him as accepted sanitary methods.

MACNALTY, A. S. Sir Thomas More as Public Health Reformer. *J. Roy. Inst. Pub. Health & Hyg.* 10, 1:7 (Jan.), 1947.

Tuck This Away — Recently a crystalline substance was isolated from a lichen; it can be administered daily without toxic effects and, when so given to guinea pigs infected with human tubercle bacilli, it seemed to retard the progress of the disease. So the search goes on for new antibiotics, to supplement or perhaps supercede streptomycin.

MARSHAK, A. A Crystalline Antibacterial Substance from the Lichen *Ramalina reticulata*. *Pub. Health Rep.* 62, 1:1 (Jan. 3), 1947.

Valuable Screening Mechanism — This quotation should tell you whether or not you will want to study the paper from which it was taken. "The smear diagnosis (of cancer of the cervix and the uterus) is important and its value has been definitely settled. . . ."

MEIGS, J. V. The Vaginal Smear. *J.A.M.A.* 133, 2:75 (Jan. 11), 1947.

Would Hospital Licensure Help? — Hospitals continue to be plagued with that most heartless of all public health tragedies, infectious diarrhea—in Massachusetts as elsewhere. Epidemiologic investigations reveal inexcusably lax techniques. Neither the cause nor the mode of transmission is known, but greater attention to this hazard by hospital administrators could accomplish wonders, say these writers.

RUBINSTEIN, A. D., and FOLEY, G. E. Epidemic Diarrhea of the New Born in Massachusetts. *New England J. Med.* 236, 3:87 (Jan. 16), 1947.

ASSOCIATION NEWS

SEVENTY-FIFTH ANNUAL MEETING
AMERICAN PUBLIC HEALTH ASSOCIATION
ATLANTIC CITY, N. J., OCTOBER 6-10, 1947

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

J. L. Murray Anderson, M.D., D.P.H., Health Dept., City Hall, Victoria, B. C., Can., Medical Health Officer, Victoria-Esquamalt Health Service
Elmer E. Bertolaet, M.D., 176 E. 2nd St., Fond du Lac, Wis., District Health Officer, State Board of Health
Arthur R. Daviau, M.D., City Bldg., Waterville, Me., City Health Officer
Robert Esty, Glen Ridge Health Dept., Glen Ridge, N. J., Health Officer
Leslie A. Falk, M.D., 790 Clemont Drive, N.E., Atlanta, Ga., Chief, Health Services Division, S.E. Region, Labor Branch, U. S. Department of Agriculture
Gerald F. Kempf, M.D., 307 City Hall, Indianapolis 4, Ind., Director of Public Health, Board of Public Health and Hospitals
Raoul D. Landry, M.D., 28 Alma St., Moncton, N.B., Can., District Medical Health Officer, New Brunswick Dept. of Health
Bernardo A. Limlingan, M.D., U. S. Marine Hospital, Carville, La., A. A. Surgeon, U. S. Public Health Service
Elbert S. Parmenter, M.D., 208 Third St., Rogers City, Mich., Director, District Health Dept., No. 4
Ardax Vahan Tajirian, Medical Dept., Iraq State Railways, Kirkuk, Iraq, Senior Health Official in charge of Railway Dispensary
R. G. Tuck, M.D., 2401 Fourth, Royal Oak, Mich., Medical Director, District No. 2
Frank E. Wheelon, M.D., District No. 1 Health Unit, Minot, N. D., District Health Officer

Laboratory Section

Victor H. Bertullo, D.V.M., Estero Bellaco 2588, Montevideo, Uruguay, S. A., Sanitary Inspector, Bureau of Cattle, Cattle and Agricultural Dept.

Major W. N. Christopher, Sn.C., Shanghai Detachment Hospital, Station Comp, AAG, APO 917, San Francisco, Calif., Chief of Laboratory Service and Preventive Medicine
Helen Fitzgerald, 599 Bedford Rd., Pleasantville, N. Y., Asst. Bacteriologist, Westchester County Dept. of Laboratories and Research, Valhalla, N. Y.
Floyd W. Hartmann, Sc.D., University of Hawaii, Honolulu 10, T. H., Chairman, Bacteriology Dept.
Joseph M. Hodges, 306 Hoke Bldg., Hutchinson, Kans., Clinical Pathologist and Medical Technologist, The Dupray Laboratory
Peter C. Issaris, M.D., 615 N. Wolfe St., Baltimore, Md., District Malarologist, Athens School of Hygiene, Athens, Greece
Marshall Levin, 58 Westland Ave., S-14, Boston, Mass., Bacteriologist, Skinner and Sherman Inc.
Dr. Alberto Montoya, Mount Sinai Hospital, New York, N. Y., Volunteer Asst. in Pathology
Juanita Powell, Box 983, College Station, Columbus, Miss., Part-time worker on Milk and Water Analysis, State Board of Health
Hazel V. Roberts, 25 Woodlawn Ave., Albany 3, N. Y., Junior Analytical Chemist, Div. of Laboratories and Research, State Dept. of Health
Edmund E. Staley, 832 El Caminito, Santa Fe, N. M., Senior Medical Laboratory Technician, Health Laboratory, University of California, Los Alamos, N. M.
Martha Wilkerson, M.A., 202 W. 38th St., Austin, Tex., Assoc. Immunologist, State Dept. of Health

Vital Statistics Section

Sidney J. Cutler, M.A., 989 Fox St., New York 59, N. Y., Senior Statistician, City Dept. of Health

- Margaret M. Fenigson, 286 High St., Passaic, N. J., Statistician
- Sara Lou Hatcher, M.A., Thompson Station, Tenn., Junior Statistician, State Dept. of Public Health
- Jorge M. deLeon, National Office of Vital Statistics, Washington 25, D. C., Staff Member, Bureau of Statistics, Guatemala City
- Claire Lingg, M.A., 2 E. 103rd St., New York 29, N. Y., Research Statistician, New York Heart Assn.
- Adele K. Polansky, M.A., 325 State St., Albany 6, N. Y., Statistician, State Dept. of Health
- Otto R. Pozdena, M.D., Bureau of Records, 125 Worth St., New York 13, N. Y., Acting Registrar and Director, Bureau of Records, City Health Dept.
- Philip G. Rettig, LL.B., 5458 Lieb Ave., Chicago, Ill., Director of Research and Legislative Services, National Society for Crippled Children and Adults, Inc.
- Robert C. Strauss, 3541 39th St., N.W., Washington, D. C., Statistician, National Office of Vital Statistics
- Lola Mai Upchurch, 420 Sixth Ave., N., Nashville, Tenn., Junior Statistician, State Dept. of Public Health

Engineering Section

- Ralph H. Baker, Jr., 192 Bartlett Rd., Winthrop 52, Mass., Graduate Student in Sanitary Engineering, Massachusetts Institute of Technology
- F. Rodwell Blaisdell, M.S., 67 Otis St., Bangor, Me., Chief Sanitary Engineer, Institute of Inter-American Affairs, Bolivia, S. A.
- Wilson F. Brown, P. O. Box 14, Forsyth, Ga., Sanitarian, State Dept. of Public Health
- James H. Drake, P. O. Box 510, Moultrie, Ga., Sanitarian, Colquitt County Health Dept.

Twelve years' experience in teaching and independent research in parasitology, immunology, and bacteriology at university medical schools and research laboratories, desires responsible position in teaching or research institution, governmental agency or industry. Write Box M-473, Employment Service, A.P.H.A.

U. S. Public Health Service Announces Examinations for Nurses

Examinations for the appointment of registered nurses to the U. S. Public Health Service will be given during March and April, 1947, in cities throughout the nation, according to an announcement made by Miss Lucile Petry, Chief of the Division of Nursing.

"The Public Health Service offers opportunities for recent graduates as well as experienced nurses," Miss Petry said.

"For the new registered nurse who can qualify here is an opportunity to acquire good initial experience. The Public Health Service offers the experienced nurse a permanent career with the advantages of professionally stimulating work, job security, regular salary increases, and opportunities for advanced study and promotion on the basis of training and ability."

Nurses interested in obtaining further details concerning appointment to the U. S. Public Health Service should write to Miss Lucile Petry, Chief, Division of Nursing, U. S. Public Health Service, Washington 25, D. C. Specific dates for examinations will be announced shortly.

Examinations for Scientists for Appointment to the Regular Corps of the U. S. Public Health Service

Seventy-five vacancies exist in grades of Assistant and Senior Assistant Scientist in

the Regular Corps of the U. S. Public Health Service. Written examinations will be held April 14 and 15, oral examinations during the period February 13 to April 9 in thirty cities strategically located throughout the United States.

Commissions are available to scientists trained in any of the following fields: bacteriology, mycology, parasitology, entomology, malacology, biology, chemistry, physiology, physics, statistics (mathematical, demographic, etc.), psychology, and for milk and food specialists.

Requirements: (1) Assistant Scientist: United States citizenship, 7 years of educational and professional training or experience, certificate or diploma from institution of recognized standing and satisfactory health, as established by physical examination. (2) Senior Assistant Scientist: As for Assistant Scientist, plus four years of additional training or experience.

Remuneration: (1) Assistant Scientist: Annual pay with allowances for dependents, \$3,811. (2) Senior Assistant Scientist: Annual pay with allowances for dependents, \$4,351. For both grades full medical care, hospitalization for appointees and families, including disability retirement, thirty days' annual leave. Periodic promotions. Retirement age: 64.

Application forms and additional information may be obtained from the Surgeon General, U. S. Public Health Service, Washington 25, D. C.

Fellowships for the Training of Health Educators

The U. S. Public Health Service announces that fellowships leading to a Master's degree in Public Health in the field of health education are again being offered. Candidates must be U. S. citizens between 22 and 40 years of age, must hold a bachelor's degree from a recognized college or university, and must be able to meet the entrance requirements of the accredited school of public health of their choice.

In addition to the degree, courses in the biological sciences, sociology and education may be required. Training in public speaking, journalism, psychology, and work in public health or a related field are considered desirable qualifications.

Tuition, travel expenses for field training and a monthly stipend of \$100 will be provided out of funds furnished by the National Foundation for Infantile Paralysis. The year's training which begins with the 1947 fall term, consists of 8 or 9 months of academic work and 3 months of supervised field experience.

Veterans are encouraged to apply and will be paid the difference between the allowance under the G.I. Bill of Rights and the monthly stipend of \$100. Employees of local and state health departments are not eligible since Federal grants-in-aid are already available for such training purposes.

Application blanks may be obtained by writing the Surgeon General, United States Public Health Service, Washington 25, D. C., and must be filed prior to March 15, 1947.

Exchange of Public Health Personnel between Hawaii and the Mainland

An opportunity for public health nurses, sanitary and medical officers to work in the Hawaii Health Department is now offered under the new exchange personnel program inaugurated by the Board of Health in the Territory.

As passed by the Hawaii legislature, the enabling act calls for an exchange of personnel for a period not to exceed a year.

Provisions in the act state that each person exchanged by the health department of any state must possess qualifications equal to the qualifications of the person exchanged for him from Hawaii and must hold in the state health department a position which is equivalent to the position held by the person exchanged for him in Hawaii.

Salaries for both exchanging parties

will be paid by the home employer. Travel, board, lodging or other such expenses will not be paid by the Territorial Health Department.

Eligible persons employed on the mainland who desire to take advantage of this exchange program are requested to write Dr. Richard K. C. Lee, Assistant Health Executive of the Board of Health, Territory of Hawaii.

Fellowships for Physicians and Engineers

The Surgeon General announces that applications for Fellowships in post-graduate public health training for physicians and engineers, for the school year beginning in the fall of 1947, will be received prior to May 1, 1947. The Fellowships are made possible through a grant given by the National Foundation for Infantile Paralysis.

The Fellowships include nine months of training in an accredited school of public health or an acceptable school of sanitary engineering followed by three months of field training.

Requirements: Under 45 years of age, United States citizenship. Physicians must have completed at least one year's internship. Engineers must have a bachelor's or higher degree in sanitary, civil, or chemical engineering, or another engineering degree with experience in public health or sanitary engineering.

The Fellowships are intended for newcomers to the public health field and are not open to employees of state or local health departments for whom federal grant-in-aid funds are already available to the states. The purpose of the Fellowships is to aid in the recruitment of medical and engineering personnel to help fill hundreds of vacancies existing in state and local health departments throughout the country.

The Fellowships are administered by the Surgeon General's Committee on Training of Public Health Personnel. Applicants may secure further details by writing to The Surgeon General, U. S. Public Health Service, 19th and Constitution Ave., N.W., Washington 25, D. C.

The U. S. Public Health Service Announces Examinations for Medical Officers

The Surgeon General announces competitive examinations for the grades of Assistant Surgeon and Senior Assistant Surgeon. Applicants must be over 21 years of age, U. S. citizens, graduates of recognized medical school and must be able to pass an oral and written as well as a physical examination.

Written examinations will be held on

March 27 and 28 at places convenient to the candidate and the Service; oral examinations before that date in various locations.

Application forms may be obtained by writing to the Surgeon General, U. S. Public Health Service, Washington 25, D. C.

New York State Holds Examinations for Public Health Nurses

A state-wide open-competitive examination for Public Health Nurse will be held sometime in April, 1947, to fill vacancies in various counties.

There are at present 148 positions available in 33 counties. Entrance salaries range up to \$2,400.

Candidates must be graduates of an approved school of professional nursing. In

addition, they must have completed an approved one year program of instruction in public health nursing, or they must have a combination of public health nursing experience and special training which in the opinion of the Public Health Council is equivalent to the year's course.

Applications must be filed with the State Department of Civil Service, Albany, N. Y., not later than March 21, 1947.

Persons who are interested in this examination for Public Health Nurse and who believe they might meet the minimum qualifications are urged to write immediately to the State Department of Civil Service, requesting application forms and a detailed announcement. A return self-addressed envelope bearing 6¢ postage should be enclosed with this request.

Opportunities Wanted

Bacteriologist; B.S., M.S. degrees; 14 years' experience in medical bacteriology, most of which has been in public health laboratories; past three years, chief bacteriologist, laboratories of state department of health; for further information, please write Burneice Larson, Director, The Medical Bureau, Palmolive Building, Chicago 11.

Chemical engineer; Master's in Sanitary Engineering; three years, chief chemist with large industrial company; four years, industrial hygienist, public health department; for further details, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Dentist who has been successful in private practice for 12 years is available; for five years served as member of state board of dental examiners; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Health educator; Bachelor of Education Degree; graduate courses in sanitation; eight years, supervisor of physical education in public schools; three years, sanitarian; past three years health educator,

municipal department of health; for further information, please write Burneice Larson, Director, The Medical Bureau, Palmolive Building, Chicago 11

Nutritionist; B.S. and Master's degree, Middle western university; several years' successful experience in hospital dietetics; four years' nutritionist with state department of health; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Well trained public health physician is available for an appointment of administrative character; A.B., M.D., M.P.H. degrees, leading schools; several years, epidemiologist, state department of health; past four years, important administrative appointment with large teaching institution; for further information, please write Burneice Larson, Director, The Medical Bureau, Palmolive Building, Chicago 11.

Public health nurse is available for administrative position in public health; Bachelor of Science in Education with major in Public Health nursing; past several years, supervisor public health staff, important war project; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

NEWS FROM THE FIELD

SANITARY RATINGS OF INTERSTATE MILK SHIPPERS

Milk shortage is a periodic condition concerning many cities. To correct this condition new producing areas are called upon frequently to augment the supply of milk coming from the usual producers. However, many health officers will not approve new sources of supply until they have been inspected and certified as meeting the standards set by the communities desiring to use these sources.

The U. S. Public Health Service is attempting to meet these difficulties by publishing quarterly a list of interstate milk shippers and supplies available for interstate shipment. The first list will appear on March 1, 1947. This action follows recommendations of the Conference of State and Territorial Health Officers for some solution to the problems mentioned above. Application by shippers for listing as well as acceptance of any listed supply in any city will be optional. To protect the accepting city, each shipper listed must be rated by the state of origin with spot checks of the state's inspection laboratory and rating procedures by the U.S.P.H.S. Ratings will be made and computed in accordance with the Public Health Service rating procedure. The rating figure listed will indicate the weighted percentage compliance with the Grade A Standards of the Milk Ordinance and Code recommended by the Public Health Service. Receiving areas operating under the Public Health Service Milk Ordinance may, in accordance with Section 11, accept as Grade A the outside sources rating 90 per cent or more providing that the bacterial counts and the temperatures of the milk upon receipt are satisfactory.

The above information is based upon a letter dated December 31, 1946, written to "All State Milk Control Authorities" by Thomas Parran, Surgeon General of the Public Health Service.

FEDERAL EMPLOYEE HEALTH PROGRAM

Public Law 658 passed by the 79th Congress of the United States makes possible the establishment of a preventive medical program for federal employees. A suggested plan for such a program was presented in a recent issue of *Public Health Reports* (61:46 (Nov. 15), 1946, pp. 1642-1654). In accordance with the Act government agencies may establish and operate or contract for the establishment and operation of health service programs. The scope of these programs is limited to

1. Treatment of on-the-job illness and dental conditions requiring emergency attention
2. Preemployment and other examinations
- 3 Referral of employees to private physicians and dentists
4. Preventive programs relating to health

The plan also sets up proposed standards and recommendations in detail for types of programs, personnel equipment, and qualities.

In January the U. S. Public Health Service announced the appointment of John W. Cronin, M.D., as head of the Federal Employee Health Division, created within the Bureau of Medical Services. The Division will develop standards and policies, review, appraise, and conduct studies of federal employee health programs. It will provide consultation services to federal agencies and contract with them to operate employee health programs. Dr. Cronin,

with the Service since 1932, has most recently been Medical Officer in charge of the U. S. Public Health Service Dispensary in Washington, D. C.

RESEARCH REQUEST

J. B. Gerberich, Department of Biological Science, Michigan State College, East Lansing, Mich., is interested in obtaining reprints, copies of unpublished manuscripts and results or observations made in connection with the biological control of mosquitoes. He wants to bring this information together in the form of annotated bibliographies.

FILMS AND FILM STRIPS ON HEART DISEASE

The Metropolitan Life Insurance Co. announces, as a part of its educational program on heart disease, a sound film strip entitled, "Jimmy Beats Rheumatic Fever" and a 10 minute motion picture, "Be Your Age." The latter was released to theaters in certain states in February and will be continued until each of the 48 states has been covered. This motion picture was prepared with the coöperation of the American Heart Association. Available with it are mimeographed copies of a suggested speech and radio dialogue useful in developing a program. The pamphlet *Your Heart* is also available for education of the general public.

As mentioned earlier in the *Journal* (October, p. 1235), material for professional groups is also available, primarily *Studies in Heart Disease*, a booklet presenting the 16 exhibit charts displayed at the July, 1946, meeting of the American Medical Association.

Requests for this material should be made to Health and Welfare Division, Metropolitan Life Insurance Co., 1 Madison Avenue, New York 10, N. Y.

NATIONAL NEGRO HEALTH WEEK

The U. S. Public Health Service announces the 33rd annual observance of

National Negro Health Week March 30–April 6. Its special objective announced for the current year is "Community-Wide Coöperation for Better Health and Sanitation." The announcement gives suggestions for organizing the week's program—broadcasts, sermons, posters, etc.—all designed to initiate the year's community health program. A list of suggested sources of coöperation is included. The health week publications are available for purchase from the Service.

For further information write National Negro Health Week Committee, U. S. Public Health Service, Washington 25, D. C.

U. S. CONGRESS CONSIDERS DEPARTMENT OF HEALTH, EDUCATION AND SECURITY

On January 10 Senators Fulbright and Taft introduced into the U. S. Senate a bill to establish the Department of Health, Education and Security, with a Secretary holding a Cabinet position. This would put all health, social security and educational functions of the government under the supervision of the new Cabinet officer. A similar bill has been introduced into the house by Representative Harris of Arkansas.

LOW INFANT MORTALITY RATE IN 1945

Final figures for 1945 published by the U. S. Public Health Service indicate the lowest infant mortality rate ever recorded for the United States—38.3, a decrease from the 1944 rate of 39.8. Provisional figures for the first ten months of 1946 indicate a further decrease of 3.2 per cent from the rate for the same period of 1945.

The five states with the lowest rates, all under 30, are in order: Nebraska and Rhode Island tied, Oregon, North Dakota, and Connecticut. The four states with a rate of more than 50 are Colorado, West Virginia, Arizona, and

New Mexico, the last named showing also the highest percentage rise, from 89 to 101.

The report issued by the Service suggests that one of the reasons for the lowered mortality rate is the 3.2 per cent increase in proportion of babies born in hospitals.

\$1,877,000,000 FOR SOCIAL WELFARE, HEALTH AND SECURITY REQUESTED

The President's budget message to the Congress of the United States requested 1948 appropriations of \$37,500,000,000. Five per cent of this, \$1,877,000,000, was requested to promote the health, welfare, and social security of the American people, chiefly through the Federal Security Agency. For the promotion of public health, including the hospital construction program, appropriations of \$203,000,000 were requested. Estimated expenditures for public health during the current year are \$170,000,000, and for 1948, \$181,000,000.

TWO MORE NATIONS RATIFY WORLD HEALTH CHARTER

The recent ratification of the constitution of the World Health Organization by New Zealand and Syria has been reported by Dr. Brock Chisholm, Executive Secretary of the Interim Health Commission. Six nations including Canada, China, Iran, and the United Kingdom have now ratified the constitution. Twenty-six ratifications are required to bring it into force.

WORLD MEDICAL ASSOCIATION

Meeting in London in September, 1946, under the auspices of the British Medical Association and the Association Professionnelle Internationale de Médecine, representatives of 21 European and 10 non-European countries formed an international organization of medical associations. To be known as the World Medical Association, its aims

are: "To promote closer ties among international medical organizations of the doctors of the world in order to assist all peoples to attain the highest possible level of health; to consider the professional problems among the profession; to organize an exchange of information on matters of interest to the profession; and to establish relations with, and to present the views of the medical profession to, the World Health Organization, and the United Nations Educational, Scientific and Cultural Organization."

NATIONAL SOCIAL WELFARE ASSEMBLY

The *Journal* has already told its readers about the organization of the National Social Welfare Assembly (July, 1946, p. 694), and its Director's Notes (Oct., 1946, p. 1111). The Assembly now has 46 constituent agencies, among which are: American Association of Medical Social Workers, American Association of Psychiatric Social Workers, American Hearing Society, American Social Hygiene Association, National Organization for Public Health Nursing, National Society for the Prevention of Blindness, National Tuberculosis Association, the Children's Bureau, and the U. S. Public Health Service. The National Health Council is one of its five associate groups. It has recently distributed a pamphlet giving the reason for its existence—to provide the central machinery through which national planning and coordination might be carried on—its antecedents, the services it is currently prepared to render and those it expects to develop. The Assembly's President is now Fred Ramsey; Donald B. Armstrong, M.D., Sallie Bright, Walter Clarke, M.D., Kendall Emerson, M.D., Shelby Harrison, Ruth Houlton, R.N., and Ellen C. Potter, M.D., are on its Executive Committee. Robert E. Bondy is the Director and the national offices are at 1790 Broadway, New York 19.

NATIONAL HEALTH COUNCIL NAMES
BAILEY B. BURRITT AS EXECUTIVE
DIRECTOR

The National Health Council, on January 30, through its president, Philip R. Mather, announced the appointment of Bailey B. Burritt, long a leader in the health field, as its executive director. Mr. Burritt will launch a program of more active leadership among the 20 national voluntary health agencies represented on the Council. The basic aims of the new program are more effective prevention of sickness and maintenance of health among the people of the United States.

An appropriation of \$78,500 by the Rockefeller Foundation has made possible the expansion of the Council's national health program.

"We are most fortunate," said Mr. Mather, Boston industrialist, "to have induced Mr. Burritt to come out of retirement and devote his unique abilities to Council activities until a national leader in public health work can be secured as a permanent director."

Mr. Burritt, who will begin his new duties immediately, was from 1914 to 1939 general director of the New York Association for Improving the Condition of the Poor, and from 1939 to 1944 senior executive director of the Community Service Society of New York. Throughout his career he has been instrumental in bringing health services within the reach of thousands of New York families.

Since his retirement in 1944, Mr. Burritt has continued many important activities in behalf of health organizations. He was president of Neighborhood Health Development, Inc., for more than a decade. He is now president of the New York Tuberculosis and Health Association; chairman of the Executive Committee of the American Social Hygiene Association; member of the Board of Directors of the Community Service Society, the Judson

Bailey B. Burritt

Health Center, and the National Tuberculosis Association; and member of the Health Advisory Council of the U. S. Chamber of Commerce.

The National Health Council, which began to function in 1921, comprises representatives from such major organizations as the National Tuberculosis Association, the American Cancer Society, the American Heart Association, the American Public Health Association, the American Red Cross, the National Organization for Public Health Nursing, and the National Safety Council. It has headquarters at 1790 Broadway, New York City, where it maintains a number of services that are available to all health agencies.

Besides working as a unifying and coordinating agency among national health organizations, the National Health Council cooperates with state and local groups in their efforts to improve health services. One of the aims of the expanded program is to make a qualified field service available to states and cities where the problem of coordi-

nation among voluntary health agencies is urgent. It is also planned to expand health education services available to member agencies of the Council.

PUBLIC HEALTH FEATURES OF CENTENNIAL, NEW YORK ACADEMY OF MEDICINE

The New York Academy of Medicine will celebrate in March and April, 1947, the 100th Anniversary of its founding. The program will reflect the profound and dramatic changes in man's mode of living and in his ways of thinking during this century. Many of the basic sciences upon which medicine of today rests were, a hundred years ago, either completely unknown or rudimentary. The major theme of the centennial will be "The Rôle of Medicine in the Changing Social Order of Today."

The preliminary program includes the following items:

March 6—Centennial Dinner—Waldorf Astoria Hotel

Guest speaker—Sir John Ryle, Professor of Social Medicine, Oxford University, England

"Social Pathology and the New Era in Medicine"

Other public health features will include:

March 19-21—Institute on Social Medicine

April 1-3—Institute on Public Health

Among the subjects to be considered at the Institute are Genetics in Public Health; Maternal Health—A Problem in Preventive Medicine; The Animal Kingdom—A Reservoir of Disease; Climate, Geography and Disease; Realities in Preventive Psychiatry; and Society's Support of the Public Health.

It is understood that the attendance at the conferences will be by invitation of the Academy.

Hermann M. Biggs Memorial Lecture by Dr. Haven Emerson of New York will take place on the evening of April 3 and will be preceded by a session of the Public Health Association of New York City.

ENGINEERING STUDENTS COURSE

Engineering students who are not interested in specific training in industrial hygiene and sanitary engineering can now obtain some knowledge of those subjects through a 12 week course offered by the Department of Public Health Engineering of the Georgia School of Technology. The Georgia School of Technology in making the above announcement recently, goes on to explain that by this training it is hoped to lessen the work of sanitary and industrial hygienists by teaching other engineers some of the problems confronting these health workers. George W. Reid, Associate Professor of Sanitary Engineering and Industrial Hygiene at Georgia Tech, will be in charge of the work, assisted by V. N. Hendrick of the Georgia State Department of Health. Three lectures a week will be given during the course.

ADVANCED COURSE IN OBSTETRIC NURSING

The University of Chicago has announced an advanced clinical course in obstetric and pediatric nursing set up to meet the increasing need for well qualified nurses to serve on advanced levels of responsibility in the field of obstetric nursing. The course is designed for both public health and institutional nurses who wish to specialize, and covers a 6 month period. The next class will be admitted March 26, 1947. For further information address Nursing Education, University of Chicago, 5733 University Avenue, Chicago 37, Ill.

BIGGS MEMORIAL LECTURE BY HAVEN EMERSON

The 1947 Hermann M. Biggs Memorial Lecture of the New York Academy of Medicine will be given on Thursday, April 3, at 8:30 P.M. by Haven Emerson, M.D., Emeritus Professor of Public Health Practice of

Columbia University. His subject will be "The Hospital Survey and Construction Act and a Nation-wide Health Program." It will be given under the auspices of the Academy's Committee on Public Health Relations at the concluding session of a three day Institute on Public Health which will be one of the features of the Academy's Centennial Celebration. At the same session Senator H. Alexander Smith of New Jersey will speak on "Government and Medicine." This session held at the Academy's auditorium, 5th Ave. and 103rd St., New York, will be open to the general public.

NURSE COUNSELING AND PLACEMENT OFFICE

The Nurse Counseling and Placement Office, New York City, reports more than 2,000 placements in its first year of activity. Established in November, 1945, this office is under the technical supervision of a full-time professional nurse consultant. Applicants served include professional nurses on a nation-wide basis, practical nurses, medical and x-ray technicians, doctors' and dentists' assistants, and physical therapists.

Six hundred and thirty-eight placements of professional nurses were made in all fields of nursing. Public health nurses were placed in urban and rural official and private agencies, both in and out of New York. Many excellent opportunities for public health nurses went unfilled because of a shortage of well qualified applicants, particularly in the fields of supervision and administration. Conversely, some well qualified applicants were not placed because of limitations they set on their availability, *i.e.*, location, type of agency, salary.

The Nurse Counseling and Placement Office has many interesting public health positions open and a number of experienced public health nurses available for placement. Employers are in-

vited to list their needs for nurse personnel; and nurses who are planning to move on to different employment opportunities are invited to register for placement. There is no fee either to employer or applicant.

Inquiries should be addressed to Nurse Counseling and Placement Office, New York State Employment Service, 119 West 57th Street, New York 19, N. Y.

INTERNATIONAL EXCHANGE OF PUBLIC HEALTH SPECIALISTS THROUGH UNITED NATIONS

Through the World Health Organization, the United Nations will initiate a system of postgraduate fellowships in public health, medicine, sanitary engineering, and nursing. Under the program, 30 postgraduate students will be selected to study for a year in the United States, Canada, and other countries.

In addition, 10 advanced specialists will receive travel grants in medicine and public health to spend three months in the United States and Canada, learning latest techniques in their fields.

This plan was recently announced by the United Nations as part of a program to spread information about the latest medical advances.

DR. N. W. VAUX APPOINTED PENNSYLVANIA STATE SECRETARY OF HEALTH

Norris Wistar Vaux, M.D., of Philadelphia has been appointed Secretary of Health in Pennsylvania by Governor Duff, succeeding Harry Weest, M.D. Dr. Vaux has until recently been Professor and Head of the Department of Obstetrics at Jefferson Medical College in Philadelphia.

DR. GILL APPOINTED ALABAMA STATE HEALTH OFFICER

D. Gordon Gill, M.B., D.P.H., Montgomery, Ala., has been appointed State

Health Officer of Alabama to succeed Burton F. Austin, M.D., who has resigned to become a staff member of the American National Red Cross. Dr. Gill, who is a graduate of the University of Toronto, received his D.P.H. from the University of Toronto in 1924, and has been the Director of the Bureau of Preventable Diseases in the Alabama State Department of Health. He is a Fellow of the Epidemiology Section of the A.P.H.A.

MENTAL HEALTH RADIO PROGRAMS

The National Mental Health Foundation has prepared a radio series—"For these we speak"—designed for sponsorship over local radio outlets by mental hygiene societies or other agencies concerned with the problem. Each program is a dramatic treatment of one particular problem with the general aim of educating the American public to a sympathetic understanding of the mentally ill. Brief introductory remarks by Helen Hayes, Harry Emerson Fosdick, Eleanor Roosevelt, and Mary Jane Ward are provided. Address inquiries to Radio Section, National Mental Health Foundation, Box 7574, Philadelphia 1, Pa.

GROWTH OF CANCER DETECTION CLINICS

With the opening of a cancer detection center in Buffalo, N. Y., late in 1946, the American Cancer Society reports that there are now 86 such clinics in 20 states under the auspices of state or local units of the Society. During the year 54 of these centers were organized. The Society estimates a total national need for about 2,500.

A cancer detection center is set up for the purpose of detecting cancer in apparently well persons who show no symptoms of cancer. As such, these clinics do not offer full diagnosis, x-ray, or biopsy. Patients showing symptoms are sent to diagnostic clinics.

Diagnostic clinics have complete fa-

cilities for diagnosis of cancer but refer patients back to their private physicians or other clinics for treatment.

The Society reports that at the end of 1946 there were 40 diagnostic clinics throughout the country, with an estimated need of about 2,250. It further estimated that there were presently 400 treatment clinics, with an estimated need of 2,000.

DR. PLOTZ, TYPHUS EXPERT, DIES

Harry Plotz, M.D., died at Walter Reed Hospital in Washington on January 6 after having suffered a heart attack while at work in his laboratory at the Army Medical Center.

During the first World War he invented the Army delouser to which every American soldier was submitted before sailing with the American Expeditionary Force.

After anti-typhus service in many parts of Europe following World War I, Dr. Plotz joined the Pasteur Institute in Paris where he not only collaborated in developing a technique for mass production of an anti-typhus vaccine but also discovered the measles virus. At the time of his death he was a consultant to the U. S. Secretary of War, having retired a year earlier as head of the virus division of the Army Medical Corps.

DR. RAJCHMAN NAMED HEAD OF UNITED NATIONS CHILDREN'S EMERGENCY FUND

Dr. Ludwig Rajchman, Polish delegate to the United Nations, and Polish representative to UNRRA, has been unanimously elected as chairman of the board of the International Children's Emergency Fund by its executive board. For 18 years director of the League of Nations Health Organization, Dr. Rajchman helped to organize the Fund as an international agency for aiding young war victims.

The executive director of the Fund

has also been announced by Secretary General Trygve Lie of the United Nations. He is Maurice Pate, who was an aide to Herbert Hoover in the first World War Relief Commission as well as in the 1945 survey of world food supplies. During the recent war years he served as President of the Commission on Polish Relief and later as Director of the Prisoners' War Relief Division of the American Red Cross.

The International Children's Emergency Fund was created by the United Nations General Assembly on the recommendation of a subcommittee representing the Social Commission of the Economic and Social Council. Its stated purposes are "for the benefit of children and adolescents of countries which were victims of aggression and of countries receiving UNRRA relief, and for child health purposes generally, giving high priority to the children of countries victims of aggression." The Fund's assets may be contributions from UNRRA, from governments and from voluntary and individual sources. Its work may be undertaken in any country only with the consent of the government concerned.

RAILROAD SANITATION GETS ATTENTION

In the spring of 1946 the Association of American Railroads organized its Sanitation Research Project, under the direction of Abel Wolman, Dr.Eng. as Consultant Director. Its purpose is to study and make improvements in railway sanitation. Its first primary objective is the development of a sanitary means of handling and disposing of sewage wastes from passenger cars. Two appointments to the staff of the project have recently been announced by Dr. Wolman: Frederick G. Whelan, Ph.D., who received his doctorate at The Johns Hopkins University School of Engineering, where he was Research Assistant and Instructor in Electrical Engineering, will serve as electrical

engineer of the project. Ralph F. Vaccaro, as bacteriologist, will supervise all bacteriological-chemical activities. He is an alumnus of the Graduate School of the Massachusetts Institute of Technology, served for 2½ years in the Army Medical Department and, since February, 1946, has been Senior Sanitary Engineering Aide in the Massachusetts Department of Public Health.

UNIVERSITY OF MINNESOTA ADDS COURSE IN HOSPITAL ADMINISTRATION

With the beginning of the current academic year, the University of Minnesota School of Public Health became the fifth university to offer a course in hospital administration. According to an announcement by Dr. Gaylord Anderson, Director of the school, the course will be open only to students holding at least a bachelor's degree. At the outset the enrollment will be limited to 20. The program will be administered by a university committee consisting of the Dean of the School of Business Administration, the Superintendent of University Hospitals, and the Director of the School of Public Health.

This new course has been made possible by a grant from the W. K. Kellogg Foundation—\$20,000 for each of three years, at the end of which time it is expected to become a part of the university's regular curriculum if it has demonstrated its value.

In announcing the new course, Dr. Anderson pointed out that the demand for competent and experienced hospital administrators far exceeds the available supply, and that as a result many administrators have come to their duties with inadequate backgrounds, resulting inevitably in inefficiency and loss of public money. He added also that positions in hospital administration usually pay good salaries.

The other schools offering similar courses are Chicago, Columbia, and Northwestern Universities and Washing-

ton University at St. Louis. Applicants in these courses are about 20 times the number that can be accepted.

Applicants for the course at Minnesota should consult with Dr. Anderson, Minnesota School of Public Health, Minneapolis.

McGraw-Hill Nursing Book Prizes Announced

Counseling Programs in Schools of Nursing, under the joint authorship of three members of the University of Minnesota faculty has been awarded the first prize of \$1,000 in the national contest sponsored by McGraw-Hill for the outstanding books on nursing. Scheduled for May publication, its authors are H. Phoebe Gordon, assistant to the director of the School of Nursing, Katharine J. Densford, R.N., director of the School of Nursing and president of the American Nurses Association, and Edmund G. Williamson, dean of students.

The second award, \$400, went to Helena Willis Render for *Nurse-Patient Relationships in Psychiatry*. Dr. Bert I. Beverly, with *A Psychology of Growth*, and Dr. Edith L. Potter, with *Fundamentals of Human Reproduction*, tied for third place and received \$100 each.

A Bill to Authorize County Health Departments in New Jersey

The January 19 *News Letter* of the New Jersey Health and Sanitary Association says, "Whether or not it is a direct result of the regional meetings sponsored by the Association, a considerable amount of interest has been evident recently in 'Better Rural Health Administration.' Perhaps the unanimous disapproval of things as they are expressed by those who attended these meetings, had something to do with it."

It then reports on a bill that has been introduced in the 1947 Session of the

New Jersey State Legislature. Prepared upon the invitation of the State Department of Health by a Joint Committee of the New Jersey Health and Sanitary Association and the New Jersey Health Officers Association, it is said to be the first attempt to move responsibility for New Jersey's local health services into larger areas of jurisdiction by using the subsidy principle. There have been earlier attempts, under a permissive law, to establish "regional units"—Multiple municipalities.

Modeled to some extent on the New York State law under which health service in rural areas is being reorganized, it authorizes the establishment of county health departments in the 14 non-urban counties of the state with populations of less than 200,000. These counties have less than one-fourth of the state's population and practically all of its rural areas.

The bill provides for one county or part-county health district in each of the 14 counties, which need not include cities with populations of 25,000 or more unless their governing bodies wish to be included, nor smaller cities if the county health officer, in coöperation with the State Director of Health, determines that their health services are adequate and efficient by definite standards to be set up. All areas in the county would participate in the tax whether included in the county services or not.

The county or part-county health district may be organized on petition of the Freeholders (Board of Supervisors) to the State Director of Health. When organized its health officer must hold a New Jersey Health Officer's license and devote full time to his work. He is assured a term of four years. The administrative body is a county board of health of 7 members, only one of whom may be a Freeholder and not more than three of whom may be physicians.

State aid to county health districts is authorized through a provision whereby, upon request of the Freeholders, the state may grant aid up to 50 per cent of the total local health department budget, but in no event to exceed \$1 per capita of the district population.

Dennis J. Sullivan, Director of the Sanitary Division of Jersey City's health services, served as chairman of the committee which prepared the bill. This committee in explaining "why this is a good bill" said in part, "The County Health Department plan has been used successfully for a long time in other parts of the country, especially in the South and West. Its advantages are now being realized in the North and East. New Jersey can benefit from many other states' experience. Our bill, if passed, will be a base on which to build conservatively and well toward one of our greatest needs—better public health in our less densely populated areas. It is for this purpose, and no other, that the bill is presented."

JOHN J. BLOOMFIELD TO BOLIVIA

The Institute of Inter-American Affairs recently announced that John J. Bloomfield, Assistant Chief of the Industrial Hygiene Service, U. S. Public Health Service, began a two month tour of duty in Bolivia as special consultant to the Institute's labor inspection and industrial health program. On request of the Bolivian Health Ministry, the Institute is coöperating in a program to improve the economic status of Bolivian workers, particularly miners. In this program Mr. Bloomfield will assist in the formulation of codes to establish safe and healthful conditions in industry and in clarification of occupational disease compensation laws.

INDUSTRIAL MEDICINE FELLOWSHIP

AT PITTSBURGH

A Fellowship in Industrial Medicine

has been established at the University of Pittsburgh School of Medicine by the Schenley Distillers Corporation, according to a recent announcement by T. Lyle Hazlett, M.D., Director of the university's Department of Industrial Hygiene. The Fellowship carries a residency of 18 months at the School of Medicine. Further particulars may be secured by writing to the Director, Department of Industrial Hygiene, School of Medicine, University of Pittsburgh, Pittsburgh 13.

NEGLECTED AREAS WILL HAVE HOSPITAL CONSTRUCTION PRIORITIES

Thomas Parran, M.D., Surgeon General of the U. S. Public Health Service, recently announced that neglected rural areas and minority groups will receive priorities in the administration of the hospital survey and construction act passed by the 1946 session of Congress. The law provides for priorities in rural areas and in localities where groups are less than adequately served because of race, creed, or color.

PERSONALS

Central States

CHARLES M. GIBBS, M.D., after serving many years, recently resigned as Greenfield, Ind., City Health Officer. His successor will be R. E. KINNE-MAN, M.D., Greenfield.

DAN MORSE, M.D., recently of Columbus, Ohio, has been appointed Medical Director and Superintendent of the Peoria, Ill., Municipal Tuberculosis Sanitarium, succeeding MAXIM POLLAK, M.D., recently resigned.

Eastern States

BAILEY B. BURRITT† was reëlected President of the New York Tuberculosis and Health Association at their annual meeting. All other officers also were reëlected for a second term. They were Vice-President, O. R. JONES, M.D.; Secretary,

MYRON I. BORG, JR.; Treasurer, H. P. DAVISON.

JAMES M. DUNNING, D.D.S.,† has been appointed Associate Dean of the Faculty of Medicine and Dean of the Harvard University School of Dental Medicine in Boston. Dr. Dunning is a graduate in dentistry from Columbia University in 1930 and has been President of the Dental Health Service of New York City. For the past year he has been a Fellow in Public Health Dentistry at the Harvard School of Dental Medicine.

SIGMUND L. FRIEDMAN, M.D.,† formerly Assistant Director, Beth Israel Hospital, Boston, Mass., has been appointed Executive Director of Sydenham Hospital, New York, N. Y., effective February 3.

D. B. GLEZEN, M.D., of Cincinnati, N. Y., has been appointed Deputy Commissioner of Health of Cortland County, N. Y., effective January 1. Dr. Glezen has been a member of the Cortland County Board of Health for 16 years and in 1946 was in charge of the department's social disease clinics.

EDWARD S. GODFREY, JR., M.D.,* Albany, N. Y., has been reappointed New York State Commissioner of Health by Governor Dewey.

FRED KARUSH, PH.D., has been awarded a three year senior fellowship by the American Cancer Society for research at New York University College of Medicine, New York, N. Y., under the direction of R. KEITH CANNON, D.Sc., Department of Chemistry. Dr. Karush has been with the Du Pont Chemical Company in New York City for five years.

I. NEWTON KUGELMASS, M.D., has been appointed Consultant Nutritionist to the Department of Health and the Department of Hospitals, New York City.

ELISE D. S. L'ESPERANCE, M.D., Head of a Cancer Clinic in the New York Infirmary for Women and Children and of a similar clinic in Memorial Hospital for the Treatment of Cancer and Allied Diseases, New York, N. Y., was awarded the 1946 medal of the American Women's Association. The medal was presented at a dinner held by 44 business and professional women's group.

AARON EDWIN MARGULIS, M.D., has been appointed Professor of Bacteriology and Director of the hospital and dispensary services of bacteriology in the New York Post-Graduate Medical School and Hospital, Columbia University, New York City, to succeed WARD J. MACNEAL, M.D., deceased.

JAMES L. MCCARTNEY, M.D.,† has been appointed consulting psychiatrist for the Great Neck Public Schools, New York, N. Y. Dr. McCartney, a veteran of the recent war, was for several years Chief of the Division of Mental Hygiene of the Connecticut State Department of Health.

JERE J. McEVILLY, M.D., has been appointed Health Officer of Little Falls, N. Y., to succeed AUGUSTUS B. SANTRY, M.D., who held the office for 25 years.

THOMAS I. PARKINSON, President, Equitable Life Assurance Society, New York, has been appointed Chairman of the National Advisory Committee of the American Heart Association. The announcement was made February 3, by HOWARD F. WEST, M.D., President of the Association. Dr. West also announced that the Committee consists of HAROLD F. STASSEN, former Governor of Minnesota and 22 prominent laymen.

ELIZABETH ANN PORTER† has been appointed Nutritionist, Bureau of Preventable Disease Control, New Jersey State Department of Health. Miss Porter was formerly with the

* Fellow, A.P.H.A.

† Member, A.P.H.A.

Pennsylvania State Department of Health as Nutritionist.

ELIAS PRATT, M.D., after 56 years of medical practice in Torrington, Conn., has presented his resignation as City Health Officer and School and City Physician, posts which he has filled for many years. Dr. Pratt has also served as President to both the Connecticut State Medical Society and the Litchfield County Medical Association.

EDWARD C. REIFENSTEIN, JR., M.D., formerly Harvard Medical School research fellow at the Massachusetts General Hospital, Boston, has been appointed Research Consultant to the Sloan-Kettering Institute for Cancer Research at the Memorial Hospital Cancer Center, New York, N. Y., and also Clinical Research Consultant to Ayerst, McKenna and Harrison, Ltd. He will carry on clinical research on the relation of glandular disturbances of cancer.

EDWARD S. ROGERS, M.D.,* assumed his duties as Dean of the University of California School of Public Health, Berkeley, Calif., in February. Dr. ROBERTS has been Assistant Commissioner in the New York State Department of Health. WILLIAM McD. HAMMON, M.D.,† who has served as Acting Dean, will continue as faculty member.

CLARENCE N. SMITH, M.D., an Officer of the regular Navy since 1918, has been appointed Industrial Medical Consultant for the eastern area of Pennsylvania for the Bureau of Industrial Hygiene, Pennsylvania Department of Health.

ROYAL W. WILLIAMS, M.D., Surgeon U.S.P.H.S. (R), has recently received a promotion to Senior Surgeon and will be in charge of the Bureau of Internal Revenue, Washington, D. C., as Chief Medical Officer.

Southern States

CHANGES IN HEALTH PERSONNEL IN ALABAMA:

A. M. SHELAMER, M.D.,† is County Health Officer of Madison County, instead of J. L. CARPENTER, M.D., as reported in the January *Journal*. Dr. Carpenter has been appointed a County Commissioner of Madison County.

CLARA ARRINGTON has been appointed as Physical Therapy Consultant on the staff of the Division of Health Services of the U. S. Children's Bureau, in Washington, D. C. She had previously served as Chief Physical Therapist in an Army general hospital treating orthopedic and other injury cases, and as physical therapy instructor at Northwestern University Medical School.

ARTHUR N. BECK has been appointed Chief Engineer and Director of the Bureau of Sanitation, Alabama State Department of Health.

JOHN F. BUSCH, M.D., Columbia, S. C., was recently appointed Assistant Chief of the Tuberculosis Division of the Department of Medicine and Surgery for the Veterans Administration in five southeastern states. For the past two years Dr. Busch has been Medical Director of the South Carolina Tuberculosis Association.

RANDOLPH L. CLARK, JR., Jackson, Miss., has been appointed Director of the M. D. Anderson Hospital for Cancer Research in the Texas Medical Center, Houston. Dr. Clark has been on the surgical staff of the Mayo Clinic and Consultant in Surgery at the Mississippi State Charity Hospital, Jackson, and the Mississippi State Tuberculosis Sanatorium. He was also Director of the Department of Surgery, AAF School of Aviation, Randolph Field, Texas, and was Chief of the Surgical Service AAF Technical Training School.

* Fellow, A.P.H.A.

† Member, A.P.H.A.

VICTOR F. CULLEN, M.D., was honored with a dinner in Baltimore, December 31, 1946, to mark his retirement as superintendent of all Maryland tuberculosis sanatoria. Dr. Cullen graduated from Johns Hopkins University Medical School and while an intern at St. Joseph's Hospital is said to have developed tuberculosis. After two years of care and treatment in a sanatorium he returned to Maryland. According to the governor, Dr. Cullen is "the father of modern tuberculosis work in Maryland." He is also a past president of the National Tuberculosis Association.

CHANGES IN HEALTH PERSONNEL IN FLORIDA:

THOMAS E. MORGAN, M.D., was appointed on January 1, as Health Officer in Duval County with headquarters at Jacksonville. Dr. Morgan was with the State Board of Health before entering the Service.

L. L. PARKS, M.D.,† who has been director of the Duval County Health Department since his return from the A.U.S., has resigned and has been appointed director of the recently organized Field Technical Staff.

JAMES H. WELLS, M.D.,† recently in charge of the Southeastern Florida Health District, was on January 1 appointed Director of the new unit composed of Brevard and Osceola Counties. His headquarters will be at Titusville and Kissimmee.

EDWARD F. REASER, M.D., formerly Assistant Superintendent of the Huntington, W. Va., State Hospital has been named Supervisor and Chief Psychiatrist at a newly established Mental Hygiene Clinic in Huntington. The Clinic has been opened by the Veterans Administration and it

is the first of its kind ever established in West Virginia.

HOWARD C. STEWART, M.D.,* Franklin, Tenn., has been appointed Health Officer of Lincoln to succeed LEROY L. FATHERREE, M.D.,* who resigned to take a similar position in Omaha.

Western States

CHARLES CALHOUN, M.D., former Health Officer of Kings County, California, has been appointed Health Officer of Tulare County. Dr. Calhoun held full-time county health offices in Virginia and West Virginia before his first appointment in California in 1943.

ELAINE A. SCHWINGER, M.D., Georgetown, S. C., has been appointed Junior Field Physician for the Territorial Department of Health of Alaska. The Territorial Health Department has announced the resignation of N. BERNETA BLOCK, M.D., Juneau, as Director of the Division of Maternal and Child Health and Crippled Children's Services.

HOWARD F. WEST, M.D., has been appointed to the newly created position of Medical Director of the Los Angeles, Calif., County Department of Charities. Newspapers report that Dr. West will serve as Medical Adviser to County Superintendent of Charities, ARTHUR J. WILL, and the Medical Directors of the various hospitals and will "Carry on scientific and professional activities relating to medical policies, problems and programs of the county." Dr. West is president of the American Heart Association and Clinical Professor of Medicine at the University of Southern California.

Foreign

PAUL F. RUSSELL, M.D.,* of the International Health Division of the Rockefeller Foundation, now assigned to service in Venezuela, has been

* Fellow, A.P.H.A.

† Member, A.P.H.A.

awarded the Walter Reed Medal for 1946 for meritorious achievement in tropical medicine. During World War II, Dr. Russell was commissioned a lieutenant colonel and was assigned to the Surgeon General's Office, where he conceived the idea of forming malaria survey units and malaria control units, the organization and training of which he planned, later going to Algiers as Director of the Allied School of Malaria and Chief Malariologist of the Allied forces in the North African Theater. He returned to the United States in 1944 and became Chief of the Division of Parasitology at the Army Medical School, Washington, D. C., until his return to civilian life early in 1946.

Puerto Rico

E. GARRIDO MORALES, M.D., DR.P.H., San Juan, has been appointed Program Director for District No. 6, Hospital Facilities Division, U. S. Public Health Service, and Consultant to the Tuberculosis and Venereal Disease Programs coöperatively carried out by the Insular Health Department with grant-in-aid federal funds.

Deaths

ADAH L. HERSHEY,* Director of the Des Moines Public Health Nursing Association for 33 years, died January 8, 1947, in Los Angeles, Calif., while on leave from her position in Des Moines because of ill health. One of her outstanding accomplishments was the developing and coördinating of city, county, and school nursing services in Des Moines and Polk Counties. The pattern developed here has been followed in many communities all over the country. Miss Hershey became a member of the

American Public Health Association in 1920 and a Fellow in 1934.

SYLVESTER LAMBERT, M.D., in retirement since 1939, died at his California home on January 10. For 20 years previous to 1939 he had served in the South Sea Islands with the International Health Division of the Rockefeller Foundation. Here he was known especially for his work in eradicating hookworm and in setting up the Central Native Medical School at Suva, Fiji.

SAMUEL MORRIS, M.D., Assistant Professor of Zoölogy at Howard University, Washington, D. C., died February 6 at the age of 51. From 1929 until 1932 Dr. Morris was instructor in zoölogy at the University of Pennsylvania and later was an instructor in biology at Temple University. He also had been professor of biology at Scranton-Keystone Junior College. During the war he was an anti-typhus specialist in the United States Department of Hygiene.

CHARLES A. O'QUINN, M.D., of Madison, Fla., died on December 9, 1946. Dr. O'Quinn had long been connected with the Florida State Board of Health as a local health officer, recently in the Taylor and Madison County Unit.

AFRANIO PEIXOTO, M.D., Professor Emeritus of Hygiene at the Rio de Janeiro University, died recently.

HOW TO LIVE

By Irving Fisher, LL.D., and
Haven Emerson, M.D.

**NEW, COMPLETELY REVISED EDITION
NOW READY!**

HOW to guard your health—your most precious possession! Let an eminent professor and a distinguished doctor tell you in plain everyday language, how to care for your body and your mind. This wonderful book, which sold 469,000 copies in earlier editions, has now been completely revised to include the latest discoveries of modern science on healthful living, and covers prevention of disease, use of alcohol and tobacco, mental serenity, mouth diseases, what food to eat, and many other topics. A really dependable book based on latest scientific fact. Get your copy today!

LaMOTTE

Standardized Buffer Salts and Standardized Buffer Solutions

These LaMotte products are the ultimate in purity and uniformity. Packaged in special containers,

they are guaranteed to give consistently accurate results. LaMotte Standardized Buffer Solutions are freshly prepared from LaMotte Buffer Salts. Concentrations are M/5 except Sodium Citrate which is M/10. Specially packaged to prevent mold growth and contamination. Container sizes 100, 250, 500 and 1000 cc.

LaMotte Standardized Buffer Salts are specially purified and standardized for the preparation of Clark & Lubs Buffer Solutions and Buffer Mixtures. Supplied in 50, 100, 250 and 500 gram containers.

Number 4

Dust and Its Control as a Means of Disinfection of Air^{*†}

THE bacterial content of dust found in homes, schools, factories, offices and hospitals varies with the different environments. Saprophytic organisms usually predominate, but parasitic and pathogenic agents may be found in large numbers. Both healthy^{1,2} and ill³ individuals more or less continually extrude bacteria into their environments in secretions and excretions from: (a) the respiratory tract (nose and throat secretions, sputum, ear, mastoid and sinus discharges); (b) the gastrointestinal and urinary tracts (feces, vomit, urine); (c) skin (scales and hair, septic skin lesions, mucous membrane, conjunctiva and vagina); and (d) wounds (discharges from septic wounds, burns and abscesses). While dust in the outside atmosphere may not be dangerous, that which is found in intramural environments inhabited by human beings should always be considered a potential source of disease agents.⁴

Rationale for controlling dust-borne organisms—Dust as a vehicle for the spread of disease agents has been studied

particularly in relation to respiratory tract infections, skin infections, and secondary infections of burns and wounds. Large numbers of hemolytic streptococci,⁵ staphylococci,⁶ pneumococci,⁷ diphtheria bacilli,⁸ and tubercle bacilli⁹ have been demonstrated in the floor dust on hospital wards. These organisms have been shown to survive in the environment for long periods of time. Little is known concerning the survival of viruses in dust. Influenza A virus, however, has been shown to survive in floor dust up to ten days without loss of its ability to produce infection in susceptible animals.¹⁰ The great proportion of organisms expelled from the respiratory tract in droplets and droplet nuclei eventually settle to form a part of the bacterial component of dust. The relative importance in the spread of disease of droplets and droplet nuclei initially extruded in the air and those raised again as dust is not known. All three modes of spread probably occur, but vary in importance with different age groups of people, diseases, environments, and seasons of the year.⁴⁰

In a recent report Wells, Winslow, and Robertson¹⁴ have classified the activities of air-borne microorganisms according to whether they invade the atmosphere on dust particles, in droplets, or in droplet nuclei. In the present

* Report of the Referee on Suppressive Measures for the Control of Dust, of the Standard Methods Committee for the Examination of Germicides and Antibacterial Agents.

† Special Review Article prepared at the request of the Editorial Board.

writer's opinion, however, there is not sufficient knowledge of the rôle which dust, droplets, and droplet nuclei play in the transmission of disease to warrant such a correlation. Employing the hemolytic streptococcus as an index of environmental contamination, it has been shown in hospital wards^{3, 11} and army barracks^{12, 13} that when small numbers of these organisms are isolated from the air they can be found in proportionately larger numbers in the floor dust and bedclothes. There is no evidence to indicate that these dried dust-borne pathogens are any less noxious than those drifting about in droplet nuclei. Certainly one cannot predict the type of infection that a given respiratory tract pathogen will produce on the basis of whether it is inhaled as dust particles recently swept into the air from the floor, as droplets recently expelled from the nose and throat, or as droplet nuclei which have been suspended in the air for some length of time.

Dust, which may carry pathogenic agents, is raised into the air by sweeping, bedmaking, and other activities, and eventually settles on all surfaces in enclosed spaces. Thus, the opportunities for spread of infection by direct or indirect contact with these "environmental reservoirs" are many. For example, in hospital wards streptococci disseminated through the air as dust-borne particles "settle out" on the furniture (bedside tables, nurses' desks, chairs, instruments, tables, carts, etc.), on food, on toys, on the skin, hands, and clothes of the patients and hospital personnel (nurses, doctors, attendants, and visitors), and again on the floor and bed surfaces.⁴ Respiratory tract infections may be acquired from the inhalation of these dust-borne organisms, or by direct transfer from a dusty surface to the nose and mouth by the hands, instruments, etc. In other situations they may settle onto exposed clean wounds and burns,

or be transferred to them directly from dusty surfaces by the hands, dressings and instruments, resulting in secondary infections.^{4, 15, 20}

There are now ample data to show that dust is an important vehicle for the spread of certain diseases of bacterial and virus etiology in the laboratory,^{16, 17} hospital wards,¹⁸⁻²¹ and army barracks.¹³ It most likely plays an equally important rôle in the spread of infections in schools and homes. Ultra-violet light,²² glycol vapors,²³ and hypochlorous acid²⁴ employed in the disinfection of air have only a limited effectiveness against dried dust-borne organisms. Therefore, the use of dust- and lint-control measures alone or in conjunction with these techniques is of importance.

Methods of Dust Control—Extensive studies by English²⁵⁻²⁷ and American investigators²⁸⁻³⁰ have shown that oil is the most highly effective and economical compound for the treatment of surfaces and fabrics for the suppression of dust and lint. A review of the literature up to May, 1944, on the development of techniques of application of oil to floors and bedclothes and the use of these dust-suppressive measures for the control of dust-borne bacteria and respiratory tract infections has been made.³¹ Since that time studies have been reported or are in the process of completion which have been concerned both with the further development and refinement of techniques of application of oil, particularly to fabrics, as well as with the control of respiratory disease among army personnel by the oiling of floors and bedding. Certain studies which were referred to in the previous report will again be discussed.

Technique of oiling floors—Most oil companies make a special grade of floor oil which meets government specifications concerning fire hazards, and which is also suitable for use on floors for dust-control purposes.³² The application of oil to floors in army barracks is

a simple procedure and can be applied with unskilled help. The floors in army barracks are usually constructed of soft wood, which absorbs large amounts of oil—approximately one gallon per 200 sq. ft.^{33, 34} The oil may be applied with a cloth mop, a rubber squeegee, or brushed on with a hair broom. Such floors maintain their dust-holding properties for as long as 8 months, provided they are cleaned only with hot water without soap or alkali.³³

The oiling of hardwood, varnished, or linoleum-covered floors requires more care. Just sufficient oil (one gallon per 1,000 sq. ft.) should be employed to leave a dust-holding surface but one which is not slippery and hazardous to the room occupants.²⁵ Such thinly coated floors, of course, will require repeated applications of oil to maintain their dust-holding efficiency. Oil may be applied to floors directly with a cloth, mop, or in the form of a sweeping compound—2 gallons of oil mixed with 100 lbs. of sawdust.²⁸ The only disadvantage to the latter method is that it is difficult to remove all the sawdust from around the legs of desks, tables, beds, and corners of the room. The writer has applied oil successfully to linoleum-covered floors in a hospital ward by daily mopping with 10 per cent oil-in-water emulsion (T-13 formula).³⁰ In one hospital study a non-oil, dust-retaining compound composed of urea, ninol, and roccal was successfully employed by daily application to the floors.¹¹ Oiled floors should be cleaned only with warm water, without the use of soap or alkali.

Application of oil to bedclothes—Data on oil-in-water emulsions for the application of oil to bedclothes and other fabrics were published in May, 1944, by English workers,³⁵ and in December, 1944, by the Commission on Air-borne Infections.²⁸ With the employment of skilled help, both formulae were found to be satisfactory for the

treatment of cotton and woolen textiles with oil. Further experience with these oil-in-water emulsions revealed certain definite disadvantages. The bedclothes treated by the English formula were found to be irritating to the bed occupants,³⁶ while the woolen blankets treated with the Commission formula developed a rancid odor due to the oxidation of oleic acid, a constituent of the emulsion base.²⁹

Further study of the application of oil to fabrics by the Commission on Air-borne Infections^{29, 30} resulted in the development of an oil-in-water emulsion known as the "T-13 formula," which contains the following:

<i>Materials</i>	<i>Parts by weight</i>
Mineral oil (Fractol A)	87
Triton NE	13

T-13 oil-emulsion base is milk-white and has the consistency of face cream. When added to water it disperses spontaneously, producing stable oil-in-water emulsions of almost any desired concentration. This formula meets essentially all the requirements of an ideal oil-in-water emulsion for the treatment of cotton and woolen textiles. T-13 oil-emulsion base can be prepared in large amounts and is stable in closed drums for long periods of time (18 months) under varying degrees of temperature. The T-13 oil-emulsion base is applied in the form of dilute emulsions as the final rinse during the routine laundry procedure without alteration in any of the steps in washing and drying of the textiles. The Fire Prevention Section of the National Bureau of Standards has certified that this oil treatment process involves no fire hazard if certain precautions are followed in drying the textiles.³⁷ The cost of treatment of textiles with the T-13 oil-emulsion base is not prohibitive, being approximately 1½ cents per lb. of wools and ⅔ cent for cotton fabrics for the initial treat-

ment, and for subsequent treatments 1/10 cent and 1/3 cent respectively. There is evidence that woolen blankets may not require a subsequent treatment, as little or no oil is removed by washing with soaps and alkalis. The oil, however, is readily removed by the dry cleaning process.³⁰

Cotton and woolen fabrics treated with the T-13 oil-emulsion base and containing from 2 to 5 per cent oil are essentially indistinguishable from untreated material in appearance, texture, touch, and odor. Over 200 skin tests with the T-13 oil-emulsion base and extensive use of oiled blankets and sheets treated with this formula by a large number of army personnel over a long period of time have shown that it does not produce skin irritation. Treated blankets containing from 2 to 5 per cent oil by weight possess marked bacteria-holding properties for several months without retreatment. Periodic sampling of oiled and unoiled blankets in army barracks for hemolytic streptococci revealed 75 per cent less positive cultures and 95 per cent fewer organisms per culture from the oiled blankets than were obtained from unoiled controls.^{30, 33}

Effect of oiling floors and bedclothes on the bacterial content of the air in barracks and hospital wards—In army barracks during the periods of maximum activity when the men were getting up, dressing, sweeping, making beds, etc., oiling floors alone reduced by approximately 70 per cent the number of air-borne bacteria compared to the number recovered from the air in the control barracks.^{28, 33} Even though the total bacterial count in the air is greatly reduced in barracks by oiling floors alone, large numbers of hemolytic streptococci may be dispersed into the air from the unoiled bedding.³³ Oiled bedding plus oiled floors effected a further reduction to about 90 per cent of the bacterial counts in the control barrack. There was a similar percentage reduction in

the numbers of hemolytic streptococci in the air of the test compared to the air in the control barracks.³³ In an army hospital ward, oiled floors and bedding reduced the numbers of beta-hemolytic streptococci by 86 per cent compared to the numbers obtained during periods when these dust-suppressive measures were not employed.¹¹ In a study on the control of streptococcal infection on a measles ward, oiling floors alone was not sufficient to prevent large numbers of type-specific streptococci from spreading about the wards. Oiling of floors, bedclothes, garments, and other articles used on the test ward, however, effected a 90 per cent reduction in the bacterial counts in the air compared to the control ward.³⁸

Oiling floors and bedclothes as a means of controlling respiratory tract infections—An investigation was carried out in an army camp in England from December, 1942, through March, 1943, on the control of respiratory tract infections by the use of oiled floors only. The average weekly infection rate per 1,000 in the test unit was 7 compared to 38 for the control. An outbreak of acute respiratory disease of epidemic proportions occurred in the control unit with no increase in the rate of infection in the test unit.³⁹

Similar studies were done by the Commission on Air-borne Infections at Camp Carson, Colorado, from March to June, 1944.³⁴ Oiled floors alone, as well as oiled floors and oiled bedclothes, were tested. Group A, comprising approximately 3,800 men in each of the test and control units, was used to observe the effect of oiled floors alone on the incidence of respiratory disease in men living in barracks. The weekly hospital admission rate per 1,000 was 4.0 for the test unit, and 5.9 for the control unit. These rates were too low to evaluate the use of oiled floors alone as a means of controlling respiratory disease.

Groups B and C were employed to evaluate the use of oiled floors plus oiled bedding. In Group B there were approximately 1,600 men each in the test and control units, and the average weekly admission rate per 1,000 for respiratory disease was respectively 6.2 and 11.5. Group C was an organization composed essentially of new recruits with approximately 350 men each in the test and control units. The average weekly admission rate per 1,000 for respiratory disease was 13.3 from the test, and 28 from the control unit. In Groups B and C, approximately 50 per cent of the hospital admissions for respiratory disease from the test and control units had throats positive for hemolytic streptococci. The number of cases and the difference in rates of admissions from the oiled barracks compared to the control were sufficiently great to conclude that oiled floors and bedding effected a significant reduction in the number of admissions for respiratory disease.³⁴

A more detailed study on the control of respiratory disease in new recruits, employing oil to floors and bedclothes, was carried out jointly by the Commission on Acute Respiratory Diseases and the Commission on Air-borne Infections at Fort Bragg, North Carolina, from October, 1944, to May, 1945.⁴⁰

During the first period of low endemic occurrence of respiratory disease there was suggestive evidence that the procedure reduced the incidence of hospitalized illness. There was little or no effect during the epidemic occurrence on acute undifferentiated respiratory disease. Hemolytic streptococcal infections and respiratory diseases of known etiology did not occur with sufficient frequency for the effect of the oiling procedures to be evaluated. The difference in the results obtained at Camp Carson compared to those at Fort Bragg may have been due to the high incidence

of streptococcal disease at the former camp.⁴⁰

Only one hospital study has been reported which has attempted to evaluate the use of dust-suppressive measures for the control of streptococcal infections. This was carried out by the English³⁸ on measles wards during the fall and winter of 1943. A preliminary 3 week period of employing oiled floors alone showed no reduction in the incidence of cross-infections on the test compared to the control ward. During the following 9 weeks, however, when dust-suppressive measures were applied to the floors, bedclothes, garments and all other cotton and woolen fabrics, a marked reduction in streptococcal infections on the test ward occurred. Group A type 6 streptococci were employed as the index of contamination of the wards and of cross-infections. During the 9 week period of study the cross-infection rate was 18.6 per cent on the test ward, and 73.3 per cent on the control, while the complication rate was only 2.8 per cent on the test ward, compared to 14.3 per cent on the control.³⁸

DISCUSSION AND SUMMARY

Little is known concerning the relative importance of dust, droplets, or droplet nuclei in the spread of disease of bacterial and virus etiology. Dust in hospital wards and army barracks has been shown, however, to become highly contaminated with certain pathogens associated with diseases of the respiratory tract, particularly streptococcal infections. The dispersion of these microorganisms into the air from floors, bedclothes, and clothes of the room occupants at the time of floor sweeping, bedmaking, and dressing, results in a general contamination of the whole ward environment, providing many opportunities for the spread of disease from direct or indirect contact with the infected dust. Little is known concerning the rôle of dust in the trans-

mission of virus diseases or other diseases of the respiratory tract of bacterial etiology.

Oiling floors, bedclothes, and other textiles is a highly effective procedure for the control of dust, lint, and dust-borne bacteria. The action of the oil is a mechanical one only. Methods are now available for the treatment of surfaces and fabrics with oil which fall within the range of practicability with respect to simplicity of application and cost. Although the most important "environmental reservoirs" of pathogens found in hospital wards are the floors and bedclothes, all surfaces (floors, tables, desk tops, etc.), as well as all textiles (blankets, sheets, pajamas, clothes of attending nurses, doctors, etc.), should be oiled to bring about the maximum dust control. The rational use of these dust-suppressive measures for the control of infections will depend on what proportion is dust-borne. Many more studies need to be carried out employing other diseases than those listed above as indices of control before oiling procedures can be accurately evaluated in relation to other methods of disinfection of air.

Studies thus far indicate that oiling floors, bedclothes and other textiles can effect a significant reduction in the incidence of respiratory tract infections of streptococcal etiology in hospital wards and army barracks. The potential hazard of dust as the vehicle for the spread of organisms found in secondarily infected wounds and burns has been emphasized by the British,^{15, 20} and dust-control measures are recommended for wards housing patients with these illnesses. No information is available as to the effectiveness of dust-control measures in preventing infection in sanatoria, industries, schools, and the home.

The magnitude of the problem of the control of air- and dust-borne diseases has been emphasized recently by

Mudd.⁴¹ The employment of these dust-laying procedures in conjunction with other methods of air disinfection, such as glycol vapors, ultra-violet light, and adequate ventilation, offers the best opportunity for their control.

Radio in Public Health

A meeting under the Chairmanship of Dr. Iago Galdston of the New York Academy of Medicine, devoted to the subject of Radio in Public Health, will be held as one of the features of the Institute for Education by Radio, at 8 o'clock on Saturday evening, May 3, at Columbus, Ohio.

At this meeting the fundamental subjects—what public health can achieve through radio, and how it can do this most effectively, will be dealt with.

Public health workers, directly and indirectly concerned with radio, are invited to attend and to participate in this Conference.

Problems and Errors in Assigning Causes of Bacterial Food Poisoning

G. M. DACK, PH.D., M.D.

Department of Bacteriology and Parasitology, and Director of the Food Research Institute, University of Chicago, Chicago, Ill.

CERTAIN bacterial agents have been implicated in outbreaks of food poisoning on the basis of presumptive and inconclusive evidence.¹ Year after year some of these same agents are reported in the literature without additional proof as to their etiological significance. As a result many misconceptions have arisen in textbooks and scientific journals regarding the rôle of such agents in food poisoning. It is the purpose of this paper to point out some of the problems in this field and to illustrate with a few examples some of the difficulties in assigning significance to these organisms.

Many kinds of microorganisms have been alleged to cause food poisoning merely because they have been found in large numbers in implicated foods, or in the vomitus or stools of patients. Some of these bacteria are natural inhabitants of the intestinal tract of healthy persons and there is no reason other than the circumstantial evidence cited for assigning them causative rôles in food poisoning. Most food at the time of eating contains many kinds of viable bacteria and certain foods may contain millions of bacteria per gram without causing illness. In the latter circumstances it should not be surprising to find the kind of organisms which are isolated from heavily contaminated food also appearing in specimens of vomitus and feces.

When illness follows the eating of a specific item of food there may have

been a lapse of many hours before a sample is collected for laboratory study. Often the food specimen is recovered from a garbage pail where it has been subject to contamination from other decaying foods and has been held at a temperature for a sufficient time to change the bacterial population from that present at the time of eating.

Another error is the failure to exclude known food poisoning bacteria or their products as the cause of illness. For example, staphylococcus enterotoxin gives rise to well defined symptoms with illness appearing 1 to 5 hours (usually 2½ to 3 hours) after swallowing the enterotoxin. There is frequently marked prostration, and in some cases shock. Vomiting and diarrhea are prominent symptoms and blood and mucus may be present in the discharges. The illness tends to be more severe when the incubation period is short. When a large number of persons presenting these symptoms is observed, it is important to rule out staphylococcus food poisoning before implicating another organism. Staphylococcus enterotoxin withstands boiling temperatures and for this reason it is possible to have enterotoxin present in a food after the organisms have been killed.

Many bacteria other than staphylococci have been assigned as causative agents in food poisoning outbreaks that were undoubtedly caused by staphylococcus enterotoxin. Although it is possible that other agents may simu-

late staphylococcus food poisoning, there has never been a clearly proven example of such an exception.

Aside from botulism and staphylococcus food poisoning which are caused by toxins preformed in food, other outbreaks of food poisoning follow the ingestion of living organisms. The symptoms and incubation period of the latter group, which include the salmonella and certain alpha-type streptococci,²⁻⁴ may not readily be distinguished or the condition diagnosed except by finding the specific agents and excluding other types of food poisoning. Too often only media selective for the Gram-negative intestinal bacteria have been used for the examination of specimens without concurrent use of media that support growth of the alpha-type streptococcus.

Recently several species of microorganisms such as paracolon bacilli,⁵ *Salmonella pullorum*,⁶ *Proteus mirabilis*,⁷ *Clostridium perfringens*,⁸ and hemolytic streptococci⁹ have been implicated as possible causative agents of food poisoning. All of these microorganisms when grown in suitable media produce substances which are toxic for animals by the parenteral route. This property of culture filtrates of various microorganisms to produce diarrhea and vomiting in animals by the parenteral route has frequently given rise to difficulty in the identification of enterotoxic material. In distinction to the above, a true enterotoxin is toxic when fed in adequate amounts to suitable animals. They may also be toxic by the parenteral route.

Since many of the above microorganisms have been implicated from time to time over a period of years, it is imperative that their rôle in the etiology of food poisoning be established. A positive solution to the problem would involve the feeding of cultures and filtrates to human volunteers. Obviously this procedure is not to be

recommended, since in the case of many members of the group of Gram-negative intestinal bacteria, their pathogenicity is unknown. Furthermore, in food poisoning outbreaks caused by certain well established salmonella species (e.g., *S. enteritidis*, *S. cholerae suis*), an occasional person may develop a systemic infection. Although there is little evidence that other species of salmonella isolated in association with food poisoning produce systemic infection, the possibility of such infections is sufficient reason for condemning such an approach to the problem.

In the absence of a direct approach involving the feeding of living agents to human volunteers, proof of the etiologic significance of an agent in food poisoning outbreaks rests upon a number of observations and tests. A careful epidemiological study is valuable, especially in outbreaks in which a single item of food may be established as a common denominator for all who were made ill. This becomes difficult in the presence of a prolonged incubation period. If an implicated item of food can be secured, it is important to know what has happened to it and whether or not it has been kept under refrigeration or has been heated since the time of the outbreak. If, by good fortune, the food has been refrigerated, then a quantitative study of the bacteriological flora should be made, including a search for all probable food poisoning agents. A search should be made for agents in the stools and vomitus of patients, and blood cultures may be desirable in infections resembling those caused by salmonella.

In the case of food poisoning agents such as salmonella, which are associated with infection rather than intoxication, there may be some valuable information collected with reference to the development of agglutinins or other immune bodies in patients recovering from attacks of the disease. The interpretation

of low agglutinin titers is unsatisfactory. In all cases where the agglutination test is employed the limitations of the test should be borne in mind, and the possibility of previous exposures or immunizations should be considered. It is well known that in mild attacks of gastrointestinal illness caused by salmonella, slight or no rise in agglutinin titers may be found in the sera of patients during convalescence.

The evaluation of the significance of a bacterium as an etiological agent in food poisoning is complicated when the organism is frequently found in the

normal intestinal tract or is a widespread saprophyte. For example, *Proteus*¹⁰ is constantly present in rotten meat, sewage, garden soil, and vegetables. This organism also is often found in human and animal feces. The numbers may be, but usually are not, markedly increased when the intestinal function is impaired. Another example is found in the case of *Clostridium welchii*,¹¹ which is present in soil, water, milk, dust, sewage, and the intestinal canal of man and animals. As a matter of fact, *Clostridium welchii* has been shown to be present in the commercial

TABLE 1

Some Outbreaks of Food Poisoning with Questionable Causative Agents

<i>Implicated Agent</i>	<i>Food Involved</i>	<i>No. Cases and Symptoms</i>	<i>Remarks</i>
Paracolon Organisms ⁵	Corn pudding	52 cases. Incubation period averaged 12 hours. Diarrhea 92.3%; abdominal cramps 75%; nausea 50%; vomiting 11.5%; recovery complete in 12 hours.	No food samples were available for examination. Stool and rectal swab specimens from 17 of 52 patients. All specimens plated on SS agar and modified tetrathionate enrichment medium: 28 single colonies of paracolon organisms isolated from 12 of 17 patients. No tests were made for alpha-type streptococci.
Cloacae-Aerogenes Group ¹⁴	Cream-filled pastry	125 cases on 2 successive days. Symptoms in every case within a few hours after eating either cream puffs or chocolate eclairs. Symptoms characterized by violent and prolonged nausea and vomiting, followed by profuse diarrhea. No rise in temperature noted. Symptoms subsided in 4-10 hours.	<i>Staphylococci</i> were found in large numbers in the filling but excluded as cause of food poisoning because of negative animal tests for enterotoxin although the symptoms are those of <i>staphylococcus</i> food poisoning. Cloacae-Aerogenes group isolated from 5 fecal specimens and from filling of 5 cream puffs or eclairs.
<i>Salmonella pullorum</i> ⁶	Rice pudding	423 cases with 172 hospitalized with symptoms of fever (av.: 102° F.), diarrhea, headache, abdominal cramps, chills, nausea, vomiting, general myalgia, prostration and backache. All patients recovered by end of 3rd day of hospitalization. No data given as to time elapsing between eating of rice pudding and onset of illness.	No food item was available for bacteriological examination. <i>Salmonella pullorum</i> was isolated in 11.7% of hospital patients and <i>Salmonella derby</i> from 0.6%. Investigation made after peak of epidemic and during convalescence of patients. No report is made of a search for other agents.
<i>Proteus vulgaris</i> ^{15 *}	Meat	209 persons affected with abdominal pain, vomiting and diarrhea coming on 12-18 hours after meal. Fever generally absent.	Isolated <i>Proteus</i> from meat specimen and from stools. Agglutinins in serum of 36 of 54 patients' serum tested in titer varying from 1-50 to 1-200 dilution. Titers in normal human serum are not included. No report is made of a search for alpha-type streptococci.

TABLE 1 (Cont.)

Some Outbreaks of Food Poisoning with Questionable Causative Agents

<i>Implicated Agent</i>	<i>Food Involved</i>	<i>No. Cases and Symptoms</i>	<i>Remarks</i>
<i>Proteus</i> ^{10 *}	Sausage	2,000 soldiers attacked with illness characterized by vomiting, diarrhea, and exhaustion. Symptoms appeared in most cases in 2-3 hours after eating sausage. Low grade fever only in severe cases which promptly subsided following treatment; 200 men hospitalized. Those who did not eat sausage were not ill nor were those who ate from the same shipment of sausage two days earlier.	Bacteriological examination of sausage revealed <i>cocci</i> and <i>Proteus vulgaris</i> . No salmonella found. Symptoms are those of staphylococcus food poisoning.
<i>Proteus mirabilis</i> ⁷	Sliced baked ham	29 cases reported and 19 hospitalized. Symptoms of severe nausea and vomiting and diarrhea. Onset of symptoms averaged 3 hours after eating. Of 19 hospitalized patients 3 passed blood; 16 had abdominal cramps; 3 had fever with a maximum of 101° F.; 16 had normal or subnormal temperatures.	<i>Proteus mirabilis</i> isolated from suspected ham and from 9 of 19 patients studied. Ham tested bacteriologically contained 62,000 organisms per gram and of this number 12,000 per gram were staphylococci. Staphylococcus food poisoning excluded because of low count. There is no record as to whether ham had been heated thus possibly destroying living organisms but not enterotoxin. Symptoms typical of staphylococcus food poisoning.
<i>Clostridium welchii</i> ¹³	Milk	Illness in babies and children characterized by fluid stools with offensive odor and by fever. Abdomen was acutely distended by gas in intestinal tract. Pus in stools.	Milk grossly contaminated with spores of <i>Clostridium welchii</i> . When non-contaminated acid milk was fed, diarrhea and abdominal distention promptly subsided and stools became normal. Symptoms suggest active fermentation process in intestinal tract with mechanical distention of the bowel giving rise to nausea and hyperperistalsis. No intoxication need be postulated.
<i>Clostridium welchii</i> ⁸	Creamed chicken croquettes from pre-cooked chicken	At least 20 people involved in 3 outbreaks. Nausea, vomiting (rare), intestinal cramps and diarrhea beginning 8-12 hours after the meal and continuing for 12 hours. Illness mentioned in one human volunteer.	Author suggests that <i>Clostridium welchii</i> may at times produce potent enterotoxin for man. (No intoxication need be postulated.) See above outbreak. ¹³
Hemolytic Streptococci ¹⁷	Ground ham sandwiches	Of 102 persons ill, 24 had scarlet fever; 56 sore throats; 7 diarrhea; 4 vomiting; 3 nausea; and 8 miscellaneous complaints.	Kittens developed vomiting and diarrhea following intravenous injection with material extracted from streptococcus ground meat cultures. When the same material was fed kittens, they remained well. Parenteral intoxication. No evidence of enteric intoxication.

* Note that these outbreaks were reported before the rôle of staphylococcus in food poisoning was fully established.

"bread starter" for salt-rising bread¹² as well as in the baked loaves. It is possible that *Clostridium welchii* in large numbers in certain foods may ferment these foods after ingestion and the gases formed cause distention of the bowel with accompanying nausea, abdominal cramping, and diarrhea. The dramatic and almost immediate response to a change in diet¹³ would suggest that no intoxication is present.

A few outbreaks which have been described in the literature are tabulated in order to illustrate some of the problems concerned with assigning bacterial agents as causes of food poisoning (see Table 1). The author is fully aware that conditions are not always ideal for definitely incriminating an organism as a causative agent. Although it is important to maintain a vigilant search for new agents, caution should be exercised in multiplying the number of agents on the basis of presumptive but inconclusive evidence.

Inactivation of the Virus of Infectious Hepatitis in Drinking Water*

JOHN R. NEEFE, M.D., MAJOR JAMES B. BATY, SN.C., A.U.S.,
JOHN G. REINHOLD, PH.D., AND JOSEPH STOKES, JR., M.D.

National Research Council Senior Fellow in the Medical Sciences and Instructor in Medicine, University of Pennsylvania; Chief, Sanitary Engineering Branch, Preventive Medicine Service, Office of the Surgeon General, A.U.S.; Principal Biochemist, Philadelphia General Hospital; Professor of Pediatrics, University of Pennsylvania

IN previous reports, the transmission of a virus of infectious (epidemic) hepatitis by drinking water to most of the residents of a summer camp for boys and girls¹ and the results of preliminary experiments on the disinfection of water containing this virus were described.² Although the epidemiological and experimental data afforded adequate evidence that the virus responsible for the summer camp epidemic was water-borne, circumstances prevented an adequate investigation of the suspected source (a cess pool) of contamination of the water supply (a deep well) at the time of the epidemic. Subsequently, a careful sanitary investigation of the relationship of the cess pool to the well provided evidence, described elsewhere,³ that the water supply could have been contaminated with sewage material from the cess pool suspected at the time of the epidemic. This finding thus fur-

ther strengthened the previous conclusions¹ based on other epidemiological and experimental observations.

The "hepatitis viruses" pass through filters which retain bacteria,^{1,4} and they have survived heating at 56° C. for at least ½ hour,⁴ have remained active for several years in materials kept in the frozen state⁵ or in the liquid state at 4° C.,⁶ and one in desiccated yellow fever vaccine was found to be active after storage for at least 1 year at room temperature.⁷ "Hepatitis viruses" in plasma or serum have remained active in the presence of merthiolate in a concentration of 1 to 2,000⁸ and in the presence of a mixture of equal parts of phenol and ether added to a concentration of 0.5 per cent.⁹ The available evidence concerning the properties of these viruses thus indicates that they are resistant to certain procedures which eliminate or destroy bacteria and suggests that certain methods of water disinfection known to be adequate for bacterial intestinal pathogens may not be adequate for the more resistant viruses.

Preliminary studies² have shown that treatment of heavily contaminated

* From the Departments of Pediatrics and Medicine of the School of Medicine and Hospital of the University of Pennsylvania.

This investigation was conducted under the Commission on Measles and Mumps, Army Epidemiological Board, with the assistance of the Sanitary Engineering Division, both of the Preventive Medicine Service, Office of the Surgeon General, War Department, Washington, D. C.

water with sufficient chlorine to produce a total chlorine residual of 1 p.p.m. after 30 minutes' contact (Lyster bag technique used for emergency disinfection of drinking water in the field) did not inactivate or attenuate a virus of infectious (epidemic) hepatitis that had been added to the water (water specimen 2, Table 2). Treatment of similarly contaminated water by the "breakpoint" chlorination technique (followed by dechlorination) apparently did inactivate this virus,² as none of the 5 volunteers ingesting such treated water developed clinical manifestations of the disease (water specimen 5, Table 2). Four of the 5 men, however, developed positive cephalin cholesterol flocculation tests between the 42nd and 67th days after ingestion of this water. Subsequently, the 5 men were inoculated with the untreated active virus and 4 of the 5 developed typical acute infectious hepatitis after incubation periods of 3 to 4 weeks. As other studies have indicated that inapparent infections unaccompanied by any laboratory evidence of hepatic disturbance may be followed by resistance to reinfection with the same virus,⁵ there is some doubt as to whether the positive cephalin cholesterol flocculation tests following the ingestion of the treated water were due to inapparent hepatitis. Because the interpretation of the positive cephalin cholesterol flocculation tests is not clear, however, and as they apparently were not technical in origin, the results indicate that "breakpoint chlorination" of this heavily contaminated water either completely inactivated the hepatitis virus or at least inactivated it to the extent that it was not able to induce clinically apparent hepatitis or resistance to reinfection.

Finally it was found² that treatment of contaminated water with sodium carbonate, aluminum sulfate, and activated carbon did not completely remove

or inactivate the hepatitis virus although some decrease in the concentration of the virus and possibly some decrease in its virulence apparently resulted (water specimen 4, Table 2).

As these initial studies suggested that the hepatitis viruses might be more resistant to chlorine than the pathogenic bacteria commonly encountered in water, and the present methods of water disinfection are based on their effectiveness in controlling the bacterial pathogens, further studies of their effect on the hepatitis virus appeared desirable. The present report deals with the results of additional studies on this problem, particularly with those obtained with different dosages of chlorine applied after preliminary coagulation and filtration.

MATERIALS AND METHODS

Preparation of Contaminated Water Specimens (Raw Specimens)—The method of preparation of the raw specimens was the same as that used in the previous experiments.² Briefly, specimens of distilled water were contaminated with the virus of infectious (epidemic) hepatitis described in previous reports^{1, 2, 5} by adding to each a similar quantity (varying from 40 to 50 parts of feces per million parts of water in the different experiments) of a feces suspension known to contain that virus. Approximately 2 ml. of a suspension of *Escherichia coli* also were added to each specimen for the purpose of facilitating a study of the effect of the treatment procedures on the bacterial counts. The raw specimens then were allowed to stand for a period of 24 hours at room temperature before further treatment was applied.

Water Specimen 6 (Control)—The raw specimen was siphoned off and passed through a pad composed of 4 layers each of sterile cotton and gauze, the object being only to remove any solid particles of feces that remained. This specimen, which was not sub-

jected to further treatment, was used as a control for specimens 7, 8, and 9, the results obtained with specimen 6 indicating those that would have been expected from specimens 7, 8, and 9 prior to treatment.

Water Specimen 7—The raw specimen was coagulated by adding 2.0 grains of sodium carbonate per gallon of water and 4.0 grains of aluminum sulfate per gallon of water. After stirring gently for 15 minutes, which resulted in the production of a heavy, promptly settling "floc," the specimen was allowed to stand for one hour without disturbance. During this period, the "floc" settled. The clear, colorless supernatant was siphoned with sterile apparatus through a sterile gauze and cotton pad into a sterile bottle. The water then was filtered through a model diatomite filter (employing a diatomaceous silica filter coat) of the type developed during the war for use by the United States Army in the field and described in detail elsewhere.³ The filtrate was received in a sterile bottle. A dosage of 3.25 p.p.m. of freshly prepared chlorine solution was applied to the filtered water and after 30 minutes' contact the total chlorine residual (measured by the starch-potassium iodide method, titration with sodium thiosulfate) was found to be 1.17 p.p.m. Using the orthotolidine test (color comparator method), the residual chlorine read approximately 1.0 p.p.m. An orthotolidine arsenite test¹⁰ indicated a residual free chlorine content slightly in excess of 0.4 p.p.m. Forty-two minutes after the chlorine had been added, the specimen was completely dechlorinated with sodium sulfite, this representing the final step in its treatment.

Water Specimen 8—Except for the addition of 25 p.p.m. of activated carbon to the raw specimen simultaneously with the sodium carbonate and aluminum sulfate and a different chlorine dosage, specimen 8 was treated exactly as specimen 7. A dosage of 7.5 p.p.m. of chlorine was applied and resulted in a 30 minute total residual chlorine content of 5.2 p.p.m. The specimen was dechlorinated 36 minutes after the chlorine had been added, this completing its treatment.

Water Specimen 9—The specimen was treated exactly as specimen 8 except for the dosage of chlorine applied. A dosage of 15 p.p.m. of chlorine was used and the 30 minute total chlorine residual was 11.3 p.p.m. The specimen was dechlorinated 34 minutes after the chlorine had been added, this completing the treatment.

Water Specimen 10 (Control)—This differed from the control specimen 6 only in that the quantity of the feces suspension

added to the distilled water in preparing the raw specimen was slightly greater for specimen 10. Raw specimen 10 was strained in the same fashion as specimen 6 and was used without further treatment as a control for specimens 11 and 12.

Water Specimens 11 and 12—A raw specimen identical with, but twice the volume of, specimen 10 was coagulated, allowed to settle, and then filtered in the same manner as specimen 7. One-half of the filtrate was removed to a separate sterile bottle. This constituted *specimen 11* which received no additional treatment. The other half (*specimen 12*) then was chlorinated, a dosage of 3.25 p.p.m. being applied. The 30 minute total chlorine residual was 2.0 p.p.m. by the starch potassium iodide method and approximately 1.5 p.p.m. by the orthotolidine test, 0.4 to 0.45 p.p.m. of this being in the form of free chlorine as indicated by the orthotolidine-arsenite test. Specimen 12 was dechlorinated by the end of 36 minutes, this completing the treatment. Specimens 11 and 12 thus both were coagulated, allowed to settle, and the clear supernatant filtered through a diatomite filter. Specimen 12, in addition, was chlorinated.

Studies on Water Specimens—Chemical and bacteriological analyses of each of the specimens were conducted by the methods described previously.² The studies for the presence of, or the effect of the treatment procedure on, the hepatitis virus were conducted in human volunteers in the same manner and under the same controlled conditions as those described previously.² The volunteers all were under 33 years of age and had no previous history of jaundice, no previous experimental inoculations, and no current evidence of hepatic disturbance detectable by history, physical examination, or laboratory tests. Isolation of the volunteers by groups was carried out as in the previous experiments.² All needles and syringes used on the volunteers for any purpose in these studies were sterilized by autoclaving for 20 to 30 minutes before each use. Following ingestion of the water specimens, the volunteers were under continuous observation and study for a minimum period of 6 months.

Summary of results of chemical and bacteriological studies made on Water Specimens 6 to 12. See Table 2 for data on treatment of these specimens. All chemical results, except pH, are expressed in parts per million. pH measured at 25° C. "Tot.," "Sus.," "Org." represent total, suspended, and organic respectively.

RESULTS

A detailed presentation of the results of the chemical and bacteriological analyses of the various water specimens is not within the scope of this paper. These results, summarized in Table 1, are considered more fully elsewhere.³

Because of the limitations imposed by the number of available volunteers, it was necessary to carry out the present studies in two parts. Water specimens 6, 7, 8, and 9 were prepared simultaneously and ingested by different groups of volunteers (groups VI, VII, VIII, and IX) in August, 1945. Specimens 10, 11, and 12 were prepared simultaneously and ingested by different groups of volunteers (groups X, XI, and XII) in November, 1945. The conduct of the two parts of the experiments at different times required the use of a control group each time (groups VI and X, water specimens 6 and 10 respectively).

The effect of the various treatment procedures on the hepatitis virus, as indicated by comparison of the results in the volunteers after ingestion of the treated and untreated (control) water specimens were as follows (Table 2):

Water Specimen 6 (untreated; control)—

Each of the 5 volunteers ingested approximately 2¾ liters of this specimen over a period of 24 hours. Three of the 5 developed typical infectious hepatitis after incubation periods of 23, 24, and 27 days respectively. One other subject developed fever, abdominal pain, anorexia, nausea, and malaise only 8 days after inoculation. Because of the possibility that the unusually early onset, if the symptoms were due to hepatitis, might be indicative of unusual susceptibility resulting in an especially severe attack, he was treated intensively (intravenous plasma, glucose, and methionine) beginning on the first day of his illness. Prompt recovery followed without the development of jaundice or significant laboratory evidence of hepatic disturbance. Excluding this case, in which the diagnosis was uncertain, the incidence of unquestionable hepatitis in this control group thus was at least 60 per cent.

Water Specimen 7 (coagulated, filtered, 3.25 p.p.m. chlorine dosage)—None of the 5 volunteers, each of whom ingested approximately 2¾ liters of this specimen, developed clinical or laboratory manifestations of hepatitis or other illness during a 6 month period of observation.

Water Specimen 8 (coagulated, activated carbon, filtered, 7.5 p.p.m. chlorine dosage)—None of the 5 volunteers, each of whom ingested approximately 2¾ liters of this specimen, developed clinical or laboratory manifestations of hepatitis or other illness during a 6 month period of observation.

Water Specimen 9 (coagulated, activated

Effect of various procedures employed in the disinfection of drinking water on a virus of infectious (epidemic) hepatitis as indicated by the incidence of hepatitis in volunteers after ingestion of such treated water. The data on Specimens 1 and 2 and on Specimens 3, 4, and 5 are from two earlier experiments (cf. 2). These data have been included to facilitate comparison with the present results. "Coagulated" refers to the treatment of water with aluminum sulfate and sodium carbonate. "Act. Carbon" indicates the use of activated carbon as an adsorbent. "Filtered" refers to filtration through a model diatomite filter with a diatomaceous silica filter coat; "p.p.m." indicates parts of chlorine per million parts of water. "N.D." represents "not determined." "Hepatitis" refers to the number of volunteers who developed unquestionable infectious hepatitis following ingestion of the various water specimens ("inoc."—inoculation).

carbon, filtered, 25 p.p.m. chlorine dosage)—None of the 5 volunteers, each of whom ingested approximately $2\frac{3}{4}$ liters of this specimen, developed clinical or laboratory manifestations of hepatitis or other illness during the 6 month period of observation.

Water Specimen 10 (untreated; control)—Of the 6 volunteers who each ingested approximately $2\frac{3}{4}$ liters of this untreated specimen, 5 developed infectious hepatitis after incubation periods of 18, 20, 21, 24, and 27 days respectively.

Water Specimen 11 (coagulated, filtered, no chlorine)—Of the 7 men who each ingested approximately $2\frac{3}{4}$ liters of this specimen, 3 developed infectious hepatitis after incubation periods of 27, 30, and 30 days respectively.

Water Specimen 12 (coagulated, filtered, 3.25 p.p.m. chlorine)—None of the 7 volunteers, each of whom ingested approximately $2\frac{3}{4}$ liters of this specimen, developed clinical or laboratory manifestations of hepatitis or other

illness during the 6 month period of observation.

COMMENT

The results show that the hepatitis virus was inactivated in heavily contaminated water treated by coagulation, filtration, and the application of sufficient chlorine to provide, after 30 minutes' contact, total and free residual chlorine concentrations of 1.1 and 0.4 p.p.m. respectively. The effect of the coagulation, settling, and filtration alone (no chlorine) was shown by the results with specimens 10 and 11. The ingestion of coagulated, settled, and filtered water was followed by a 43 per cent incidence of hepatitis. This represented a 40 per cent decrease in the

incidence as compared with that observed in the control group following ingestion of the untreated contaminated water. In a previous experiment,² coagulation and settling alone (water specimen 4, Table 2) also decreased the incidence of hepatitis by 40 per cent as compared with that in the group receiving untreated water (specimen 3). Although the groups are too small for the results to be statistically significant, the occurrence of a decrease in incidence in two consecutive similar experiments suggests that this part of the treatment had some effect on the virus. This effect probably was chiefly the result of a decrease in the concentration of the virus as the absence of any apparent difference in the severity of the disease resulting from specimen 11, as compared with that in the control group (specimen 10), suggested that the virulence of the virus was not appreciably influenced. It is of interest, however, that the *minimum* incubation period in those who received the coagulated, settled, and filtered water was 27 days whereas the *maximum* incubation period in the control group (water specimen 10) was 27 days (Table 2). This also was observed in the previous similar experiment, the minimum incubation period in those receiving coagulated and settled (but not filtered) water (water specimen 4, Table 2) being 33 days as compared with a maximum incubation period of 22 days in the control group (water specimen 3). Combining these two similar groups who received coagulated and settled (specimen 4) or coagulated, settled, and filtered (specimen 11) water and the two respective control groups (specimens 3 and 10), the mean incubation period for the former was 31.6 days (5 cases) and that for the latter was 21 days (9 cases). The minimum incubation period of 27 days in the former group was observed in only 1 case, the period in the other 4 ranging from 30 to 37 days. The maximum in-

cubation period in the combined control groups was 27 days, the period in 7 of the 9 cases ranging from 19 to 22 days. In spite of the small size of the groups involved, the difference in the mean incubation periods is statistically significant and shows that this type of water treatment (regardless of whether the effect was due to decrease in concentration of the virus, its virulence, or both) resulted in an appreciable increase in the length of the incubation period. Although not demonstrated conclusively, the data suggest that this was due chiefly to the coagulation and settling part of the procedure, the results with water that only had been coagulated and settled being similar to those with water which had been coagulated, settled, and filtered. The failure of this type of filter to remove the hepatitis virus, which passes through Seitz and other bacteria retaining filters, is not surprising as the diatomite filter did not retain bacteria (Table 1, bacteriological studies), although the bacterial count apparently was decreased by such filtration.

It is obvious, therefore, that the complete control of the hepatitis virus (and probably other infectious agents) in drinking water depends, in the final analysis, almost entirely on the disinfectant used and its proper application. These studies have shown that the application of sufficient chlorine to provide, after 30 minutes' contact, a total chlorine residual of approximately 1 p.p.m. and a free chlorine residual of 0.4 p.p.m. was capable of inactivating the hepatitis virus in heavily contaminated water when the water had been treated previously by coagulation, settling, and filtration. The minimal effective dose of chlorine under these conditions was not determined due to the lack of volunteers and the more urgent need of determining a reliable method for use by the army in the field.

Although the lowest dosage of chlorine applied, in these experiments, to coagulated, settled, and filtered water was effective in inactivating the hepatitis virus, the resulting total residual chlorine concentration was greater than that ordinarily required in municipal water practice. Conclusions regarding the adequacy, in respect to the hepatitis virus, of smaller doses of chlorine must await the determination of the minimal effective dose in coagulated and filtered water. It is significant however, that the 30 minute residual total chlorine concentration of 1 p.p.m., shown to be effective in coagulated, settled, and filtered water, failed to inactivate or attenuate this virus in previously untreated water.² The difference between the effect of the same total residual chlorine in untreated water as compared with that in previously coagulated, settled, and filtered water may be due in part to a conversion of most of the free chlorine to chloramines, which are known to be less active disinfectants than is free chlorine, by the greater quantity of unoxidized organic material in the former. This indicates the importance of proper pretreatment (coagulation, settling, filtration) of water, particularly if polluted water is the original source, in order to decrease the quantity of unoxidized organic materials before chlorine is applied.

These observations permit some speculation about a possible source of origin of some small outbreaks of infectious hepatitis and of some of the apparently sporadic cases. It is emphasized that the following observations are entirely theoretical and not based on factual evidence. As the virus of infectious hepatitis is excreted in the feces of infected persons and some communities use polluted streams as the original source of their water supply, it appears possible that any break or inadequacy in the numerous steps concerned in the preparation of such water

for human consumption might permit the survival of small quantities of hepatitis virus. Considering some of the many factors that may be involved—polluted water as the original source, probable wide variation in the degree of pollution, the final dependence of adequate disinfection on the quantity and efficiency of the disinfectant (chlorine) used, this in turn dependent on the composition of the water; variation of the composition with the degree of pollution and the efficiency of the coagulation and filtration procedures, the limitation imposed by palatability (taste, odor, etc.) on the quantity of disinfectant that can be used, the resistance of the hepatitis virus (and possibly some other viruses) to procedures which ordinarily destroy or eliminate bacteria, and the necessity of supplying large quantities of water continuously without interruption—it would not be surprising if small quantities of some of the more resistant infectious agents occasionally survived. This could account for some of the occasional small outbreaks of hepatitis or for apparently sporadic cases at widely separated points served by the same source of water.

SUMMARY AND CONCLUSIONS

1. The effect of certain procedures commonly employed in the disinfection of drinking water on a virus of infectious (epidemic) hepatitis has been investigated with the following results:

- a. Coagulation, settling, and filtration (diatomite filter) of contaminated water did not eliminate or inactivate the hepatitis virus as the disease developed in 40 per cent of the volunteers who ingested such treated water. However, this treatment resulted in a prolongation of the incubation period and a 40 per cent decrease in the incidence as compared with that in the control group.
- b. The application to such water (previously coagulated, settled, and filtered) of sufficient chlorine to provide, after 30 minutes' contact, total and free residual chlorine concentrations of 1.1 and 0.4

p.p.m. respectively apparently was adequate to inactivate the hepatitis virus under the conditions of this experiment. However, the same 30 minute residual total chlorine concentration (1 p.p.m.) in contaminated water that had not been pretreated by coagulation, settling, and filtration did not inactivate the hepatitis virus.

2. The complete control of the hepatitis virus (and probably other infectious agents) in drinking water depends almost entirely on the disinfectant as the virus is not eliminated or inactivated by preliminary coagulation, settling, and filtration of the water. The efficiency of the disinfectant varies with the character of the water and the resistance of the infectious agent concerned. Dosages of chlorine that are adequate for inactivation of the bacterial pathogens occurring in drinking water may not be adequate for the hepatitis virus, particularly if the water has a high content of unoxidized organic material. Conclusions regarding the adequacy, in respect to the hepatitis virus, of the dosages of chlorine ordinarily applied for the disinfection of water must await the determination of the minimal effective dose of chlorine in coagulated, settled, and filtered water.

ACKNOWLEDGMENT: These investigations were made possible through the cooperation of the administrative staffs of Selective Service (Camp Operations Division), the National Service Board for Religious Objectors, the American Friends Service Committee, the New Jersey State Hospital (Trenton, N. J.), and the Philadelphia State Hospital. We are particularly indebted to the members of the technical staffs of our laboratories in the

Hospital of the University of Pennsylvania and in the New Jersey State Hospital, Trenton, N. J. The assistance of various members of the staffs of the Biochemical Laboratory of the Philadelphia General Hospital, the William Pepper Laboratory of Clinical Medicine of the Hospital of the University of Pennsylvania, and the Laboratories of the New Jersey State Hospital in the conduct of certain phases of the studies is greatly appreciated. Finally, the authors gratefully acknowledge the contribution made by the members of the Civilian Public Service Unit No. 140, Philadelphia, Pa., who served as experimental subjects as well as assisting in the conduct of a large part of the technical work connected with the investigations.

Investigations of the Swab Rinse Technic for Examining Eating and Drinking Utensils*

LEON BUCHBINDER, PH.D., F.A.P.H.A., THEODORE C. BUCK, JR., PERCY M. PHELPS, F.A.P.H.A., RAYMOND V. STONE, D.V.M., F.A.P.H.A., AND WALTER D. TIEDEMAN, M.C.E., F.A.P.H.A.

Department of Health, New York, N. Y.; City Department of Health, Baltimore, Md.; State Department of Health, Grand Rapids, Mich.; Los Angeles County Department of Health, Los Angeles, Calif.; and State Department of Health, Albany, N. Y.

AT the Annual Meeting of this Association in 1943 the Subcommittee on Food Utensil Sanitation of the Committee on Research and Standards submitted a revision of the technic for the bacteriological examination of food utensils.¹ Suggestions and criticisms were invited with a view to making further modifications so as to get the technic in generally acceptable form for standardization.

The chairman of that subcommittee reports having received many suggestions, that ranged from one to the effect that the technic was not precise enough, to one that it was too complicated for ordinary use. The suggestions for changes in the technic emphasized the need for more factual information to determine the need for standardizing various details of the technic and the values to be set.

A series of studies was suggested to secure the required data which the members of the subcommittee were not in a position to undertake. The newly

organized National Sanitation Foundation undertook to sponsor this work which has been done by the group submitting this paper. The work has not been completed, but enough has been accomplished to justify this report of progress. Further comments will be welcomed and given consideration in completing the work.

At the outset it should be stated that the purpose of this work is not to recover the greatest number of bacteria possible from washed and sanitized utensils but to develop the technic that is likely to reveal the presence of relatively few bacteria on utensils and to give the most nearly uniform results under all conditions in the hands of average laboratory technicians.

Each of the four participating laboratories undertook to run a series of critical tests of the various details of the technic, particularly those that have been questioned. Among these details are the time interval between swabbing and plating, the use of wood or wire applicator rods, the number of times each surface should be covered by the swab, whether the direction of each stroke in swabbing should be the same

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 11, 1946.

or reversed, the area of plates to be covered and the need for a template to measure such area. Other details are the buffering of the distilled water to be used and the type of agar. The possible effect of caps and the applicator sticks on the pH of the rinse and therefore on the count. Another point to be investigated is the time of survival of bacteria on utensils to be swabbed.

In order to secure soiled plates, cups, glasses, forks, and spoons for testing that would have similar numbers of organisms on them a procedure was adopted for soiling them. A quantity of water was collected from the wash water tank of a dishwashing machine in a restaurant after it had been used for an hour or more for washing dishes. A sample of this water was plated in order to get an approximation of the number of bacteria present while the main portion was being held in a refrigerator to lessen the growth of bacteria. After 24 hours, when an approximation of the number of bacteria present was obtained, the water was diluted to an extent determined by trial so that the desired number of bacteria were left on test utensils. Carefully cleaned and dried and sterilized plates, cups, glasses, forks, and spoons were submerged in this diluted dish water and then allowed to drain and dry.

In much of the work an effort was made to have the counts on these soiled utensils fall somewhere near the common standard of 100 per utensil as this is the critical range in which the greatest consistency is desired. Furthermore, the significance of differences in counts is more apparent in the lower range.

Buck found that wash water with a high detergent content, that is, with a pH above 9.6, produced colonies of the spreader type and was not suitable for this work. He also reports finding thermophylic organisms in the wash

water and that the recovery of organisms from utensils soiled with high count wash water was surprisingly low. Stone found the use of soiled wash water from dishwashing machines to be unsatisfactory due to the difficulty in securing it without alarming operators, to variations from meal to meal in such things as fat content, and to the fact that alkalinity and temperature determined the type of organisms surviving. Stone also had trouble with thermophiles. Furthermore, the organisms in this soiled water did not adhere well to the utensils. Stone used cultures of coliform bacteria and staphylococci in an inert gum called carboxy methyl cellulose. This gave an excellent soiling medium that adhered well to the surface and yielded nicely to swab collection after soiled rims were inverted for several minutes in a pan of water.

The proposed technic required the plating of samples of the rinse water within 4 hours after swabbing. This precludes the shipment of rinse samples to laboratories and limits the usefulness of the test. This provision was based on work which showed that a single species of bacterium died off in the rinse water. As has been indicated wash water from commercial dishwashing machines or a mixed culture of coliform organisms and staphylococci was used in making this test. These are organisms more likely to be found on utensils washed by machine than that used in previous tests. Generally thermoduric or thermophylic organisms predominate. The work of all the investigators on the delayed plating of such rinse water shows that when held at refrigerator temperature the count at the end of 24 hours did not vary greatly from that at the end of 4 hours. This was true whether the count was low or high. There were variations in individual tests. The differences between counts obtained by plating portions of any one sample at 4, 8, and 24 hours

are close enough, however, to make it unimportant when the plating is done within a 24 hour period. It is necessary that the sample be refrigerated because at about 75° F. growth was found to be profuse after 8 hours. Figure 1, prepared by Buchbinder, gives a summary of the results on all utensils of four experiments with rinse samples held at refrigerator temperatures and of three experiments with rinse samples held at about 75° F.

Considerable doubt has been expressed as to the length of time that organisms left on utensils during the washing and sanitizing processes will remain viable. In two experiments with low count utensils, Buchbinder found that plates stored unstacked in an open room showed a marked increase in count during the first 3 hours whereas all other utensils showed little variation during the first 24 hours. Three experiments with high count

FIGURE I

EFFECT ON COUNT OF TIME OF PLATING RINSE SOLUTION
IN PERCENTAGE OF INITIAL COUNT (BUCHBINDER)

dishes showed a similar increase in count on plates during the first 3 hours followed by a decrease to about the original number during the next few hours, and then a fairly constant status for 24 or 48 hours. Other utensils with high counts, however, showed a decrease in count during the first 6 hours, averaging about 70 per cent, which leveled for utensils stored in a closet. The low count utensils which are of special interest to enforcement officials, generally showed proportionally higher counts after storage than did those with original high counts. Comparative tests on utensils stored without stacking out of the direct sunlight in an open room and in a dark closet showed little difference in the general trend. Both high and low count plates, whether kept in a room or in a closet, increased in count considerably during the first 3 hours. However, high count plates stored for 24 hours gave within 30 or 40 per cent of the original count whether kept in a room or dark closet. Increases in counts on storage must indicate either deposition of air-borne bacteria or growth. Buck reports that as many as 300 organisms were deposited in 24 hours on an open agar Petri plate. However, he too found a considerable decrease in the number of organisms remaining on utensils after 24 hours.

In practice most utensils would be examined at the time of an inspection made between breakfast and lunch or between lunch and dinner or within 4 hours after they are washed. This work indicates that if a utensil were entirely free from organisms after being washed and sanitized and were stored in a clean place as required, it should not pick up more than the usually allowable 100 organisms per utensil from the air. If more should accumulate, however, the air-borne organisms would be objectionable since their presence would indicate improper handling. Furthermore, the

rate of dying off of organisms, whether stored in a light or dark place, is not so great that a utensil with an initial count much greater than 100 is likely to show a satisfactory count after standing for 4 hours. Moderately high counts might change, however, to passing counts in this time.

The proposed technic specifies the use of wooden applicator sticks the lengths of which are not fixed. These sticks are broken off before shaking, which allows sufficient disintegration of the cotton swab during shaking. Some workers were reluctant to change from stainless steel wire to the use of wood for this purpose without more factual evidence of the need for changing. The use of cotton is specified without saying what kind of cotton, although this may make considerable difference. Tests were run using wooden applicator sticks and stainless steel wire ones. The cotton was removed from the wire rods with sterile forceps for a third comparison. In 59 tests on various utensils Buchbinder found that in 39 instances those tests made with wood applicators gave higher counts than the metal ones, the same count in 4 instances, and lower counts in only 16 trials. This constituted a significant difference in favor of wooden applicators. When the cotton on the metal applicators was removed with sterile forceps to permit more complete disintegration, the tests made with wooden applicators gave higher counts in only 29 instances, the same counts were obtained in 11 tests, while tests made with metal rods gave higher counts in 19 instances. This difference is not mathematically significant. However, the work of detaching the cotton takes considerable time and Buchbinder, therefore, favors the use of wooden applicators broken off before shaking. The work of the other investigators was in agreement and they also concluded that the use of wooden applicators is desirable. Buck and Kaplan²

have proposed the use of a simple sterile cutting device for this purpose. Stone points out that the flexibility of the wood in conforming to the shape of the utensil also is an advantage in making good contact with the whole surface to be swabbed.

Stone conducted some experiments designed to compare absorbent cotton, non-absorbent cotton, and glass wool as swab material. It is clear that the material used must perform the somewhat conflicting tasks first of snaring bacteria and then of releasing them as completely as possible in the rinse water. At best many organisms are retained in the cotton after shaking. Stone's work indicates that non-absorbent cotton gives the most uniform results of any of the three materials tested.

The proposed technic does not include a requirement as to the pH of the rinse solution after sterilization which appears to be of considerable importance. When bakelite caps on screw cap vials were substituted for aluminum ones Black found that some of these caps would not withstand sterilization and that many of them changed the pH of the sterilized rinse solution. Black found a source of mineral filled bakelite type caps which stood the test of withstanding sterilization without releasing any chemical that would affect the bacteria in the rinse solution. Similarly, Phelps reports that both applicator sticks and cotton in the swab may affect the pH of the rinse solution to increase the acidity of the rinse solution. He found a standard baby swab that had little if any effect on the pH. It may be necessary to specify materials and to require the spot checking of the pH of the rinse solution in vials after sterilization with the applicator and cotton in place.

The proposed technic provides for running the swab slowly and firmly 3 times over the surface to be examined. Questions have been raised as to

whether the direction should be reversed between strokes and as to whether better uniformity might be obtained by increasing the number of strokes. In a series of two experiments with high count utensils and three with low count utensils Buchbinder found that counts increase progressively with the number of strokes. He found that with high count utensils the mean count with 5 strokes was about 60 per cent greater and with 10 strokes, 80 per cent greater than the mean count obtained with 3 strokes. Similarly on low count utensils the mean count with 5 strokes was approximately 20 per cent greater and with 10 strokes, 30 per cent greater than that obtained with 3 strokes. It also was found that with high count utensils (between 40,000 and 100,000), reversing the direction of strokes decreased the count in all tests, whereas with low count utensils (between 800 and 1,200), reversing the direction between strokes increased the count from 5 to 15 per cent. In covering an area of 4 square inches Buck recovered more than 3 times as many organisms using 10 strokes reversing directions between strokes as he obtained with 10 single strokes in a single direction. It is evident that further standardization of this detail of the method is desirable. It also is suggested that additional thought be given to making the areas swabbed on utensils of different types nearly equal within practical bounds.

Among the criticisms of the proposed technic that were received was one to the effect that the entire surface of plates should be swabbed. This point is to be investigated but the work has not been completed.

Another point criticised was that the use of metal templates, which require flaming between use, to measure a 4 sq. in. area was too laborious. It was suggested that an approximation would do as well. Buchbinder found that counts made by swabbing 4 sq. in.

by template and 4 sq. in. by guess were similar. He noticed a tendency to overswab by guess, but this had no serious effect on the results. Buck also reports little difference between counts on plates similarly soiled with results obtained by approximating the 4 sq. in. area and by fixing the exact area by template. In this connection if exact measurement should seem desirable the use of single service sterilized templates made of Kraft paper has been suggested.

Stone reports some work on the composition of the medium to be used in plating the rinse solution. The proposed technic specifies the use of standard tryptone glucose extract agar (without milk). Media suggested for investigation are the old nutrient agar consisting of 3 per cent beef extract, 5 per cent peptone and agar without dextrose, the same with tryptone and dextrose, the same with tryptose and dextrose, and the same with neo-peptone and dextrose.

Some work in the investigation of the composition of the buffered distilled water has been done and more is contemplated. Special attention is being given to the possibility of adding a neutral wetting agent.

SUMMARY

An important decision reached is that if the samples of rinse water are kept at 40° F. or less without freezing, plating at any time within 24 hours after sampling is satisfactory. This makes the test available to those who have found that the best time to collect samples at bars is during the evening rush hours and also to those who must ship samples to the laboratory. The work also shows that there are sound reasons for requiring the use of 3 inch long wooden applicator sticks broken off before plating; for specifying the use of non-absorbent cotton; for controlling the pH of the rinse water as ready for use, that is taking into account any effect of the cap, applicator

stick, and cotton. Enough of the bacteria on dry utensils will persist for 4 hours or more, or for the usual interval between the morning and noon, and noon and evening meals, to make it possible to detect the use of ineffective washing and sanitizing processes. It is recognized that some deposition of airborne bacteria on such utensils is likely to occur.

It also is evident that increasing the number of strokes in swabbing increases the number of bacteria recovered from the surfaces of utensils, and it makes a slight difference whether the strokes are reversed or are all in the same direction. In other words this detail must be standardized. The work indicates that whether the area swabbed on plates is measured by template or approximated is not of great importance. The use of a template involves extra equipment and work. Also areas on cups and glasses are approximated.

The work is not completed but there is a good prospect of getting it done within the next year. Although the final determination of the medium to be used for this work may be influenced greatly by the media used in public health laboratories, for other work a farther comparison of media is desirable. Further standardization of a soiling medium for this work also is desirable as is more work on the composition of the buffered distilled water.

After the Subcommittee on Food Utensil Sanitation has reached a decision as to the details of the revised technic some critical work should be done to determine the degree of uniformity that may be expected in the use of the technic.

Dishwashing Practice and Effectiveness (Swab-rinse Test) in a Large City as Revealed by a Survey of 1,000 Restaurants*

HYMAN J. KLEINFELD, PH.G., AND LEON BUCHBINDER, PH.D., F.A.P.H.A.

Bureaus of Food and Drugs and Laboratories, Department of Health, New York, N. Y.

THE purpose of this survey was to obtain a representative picture of dishwashing practice and effectiveness in New York City. This, as far as is known, is the first large-scale study carried out in a large city. It was hoped that analysis of the findings obtained might indicate a program for the improvement of eating utensil sanitation in this city.

TECHNIC

A total of 1,005 restaurants were studied and 3,657 swab samples of utensils were secured in the years 1944 and 1945. This was prior to the present clean-up program of the Health Department. The first 196 restaurants examined were chosen by locality or to check a given type of establishment or process. The remainder were chosen by selection of every 20th card from an alphabetical card index file of approximately 20,000 restaurants in New York City.

Dishwashing efficiency was determined by means of the swab-rinse test. The technic of swabbing of utensils followed the procedure recommended by the U. S. Public Health Service.¹ The

maximum interval of 4 hours between sampling and plating recommended by the U.S.P.H.S. was adhered to in most instances, but in a few unavoidable instances the interval was extended to 5 hours.

Although every effort was made to obtain freshly washed utensils for swabbing, this was not always possible, particularly when samples were taken during rush periods. As a result, utensils tested were frequently selected from those ready for service and no information was available as to the elapsed time between washing and sampling. In studies now being carried on in this laboratory it has been clearly shown that there is a marked reduction in the number of recoverable bacteria while utensils are drying, and that the death rate is maintained at a reduced but appreciable level for a number of hours after the utensils have dried.² If it had been possible to secure uniformly freshly dried utensils for sampling, a more accurate picture of dishwashing effectiveness might have been obtained.

The procedure for the examination of the swab samples in the laboratory followed that of the proposed method of the A.P.H.A.³ The major deviation from this technic was that metal swabs were used instead of wooden ones. This

* Presented before the Engineering Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 12, 1946.

technic fails to reveal the presence of as many organisms as does the use of the wooden swab.²

DESCRIPTION OF TYPES OF RESTAURANTS AND WASHING EQUIPMENT

The restaurants visited during the survey are arbitrarily sorted for description and analysis of the data obtained into five categories: cafeteria, waiter service, bar, luncheonette, and open stand.

Cafeterias—These restaurants are usually large and of the self-service type, i.e., ones in which patrons select silverware from an open tray, glasses from racks at a drinking fountain, and food from a counter. Cups are the only utensils sampled which are distributed individually by the cafeteria personnel.

Waiter Service—This category includes restaurants where food is served by a waiter to patrons seated at tables, as distinguished from cafeterias where patrons serve themselves, and luncheonettes where they usually are served at a counter. Included in this group are the most expensive restaurants in the city. Waiter service establishments may have bars, and if so, bar glasses were sampled.

Bars—The serving of liquor is the main business in this type of restaurant, while the serving of food is incidental. Frequently knives, forks, and cups which may not have been used for a long time were sampled at these establishments. Glasses, on the other hand, were often sampled from the drain board immediately after the washing process.

Luncheonettes—Most of the patrons in this type of establishment sit at a counter although some may be served at tables. These are usually small establishments and include the so-called diners (dining cars).

Open Stands—This type of establishment usually has no seats and the patron is served, from an open counter facing the street, with coffee, sandwiches, frankfurters, cold drinks, etc.

DISHWASHING

The two main types of dishwashing operations found were hand washing and machine washing. The washing of glasses and crockery was carried out in one of the following ways:

Hand Wash—The usual type of washing equipment consists of a two compartment sink. One compartment is designed as a wash sink and the other as a rinse sink. This latter is usually equipped with a gas burner underneath, the function of which is to maintain the water in the sink at a temperature of 180° F. and with a wire basket for holding dishes in this scalding water. Another type of sink used has three compartments. The functions of the three compartments are those of washing, rinsing, and scalding.

Machine Wash—Four distinct types of machine washing operations were observed.

Counter Type Machine—This machine is a simple rinse spray and has no recirculating tank. Water is sprayed from nozzles connected directly to a city water line without auxiliary pumping. Some machines have a device for mixing hot and cold water and others a device for mixing detergent with the rinse water.

Single Tank Machine—This machine, which may be either of the "push through" or "closed door" variety, has a wash tank, which should contain water and a detergent, and a separate rinse spray. The wash tank water is recirculated and sprayed on the utensils by a pump. Thus, the same water is re-used for variable periods of time on succeeding batches of utensils. Rinse water is sprayed directly from a city water line without additional pump pressure. The rinse water drains into the wash tank thus constantly diluting its content of both soil and detergent.

Double Tank Machine—This machine has a wash tank and a rinse tank and a final so-called curtain rinse spray.

Water from each tank is recirculated separately by force pumps and sprayed onto the utensils. The final rinse comes directly from a city water line and drains into the rinse tank.

Triple Tank Machine—This machine has three tanks with a pump for each. The first is a wash tank and the others are rinse tanks. There is also a final curtain rinse.

Silverware was found to be washed by hand or machine in one of the following ways:

Hand Wash—The soiled utensils are usually first dropped into a wooden tub containing water and allowed to soak. They are then placed in a wire basket, plunged into soap solution, and rinsed in hot running water. A superior hand washing technic makes use of a series of two cylindrical sinks, each of which is heated by means of a steam jet, steam jacket or gas burner. The utensils, which are handled in wire baskets, are plunged into and shaken in a strong soap solution in the first sink and then rinsed in steaming hot water in the second sink. After rinsing they are emptied on cloths and are then usually dried with a towel.

Machine Wash—Silverware may be washed mechanically by either of the following methods: (a) spread in a single layer in shallow metal trays and passed through a standard spray type washing machine, or (b) washed in a special silverware washing machine. The latter machine consists of two main parts. One is a cast iron cylinder, with perforations and a removable end, in which silverware is placed together with a detergent. The other is a horizontal tank into which the cylinder is placed. The tank is closed and the cylinder rotated by gears connected with a motor. A slow stream of hot water mixes with the detergent and washes the utensils. When the water valve is opened fully, the utensils are automatically rinsed. Finally, hot air under pressure is ad-

mitted to dry the utensils. This last step is automatically timed.

A number of establishments which wash by hand or machine also burnish their silverware at intervals with a special machine. This technic also promotes better bacteriological cleanliness of silverware.

RESULTS

All the swab-rinse data are summarized briefly in Table 1 where they are listed under the categories of hand washing and machine washing. The number of samples of the several types of utensils studied which meet the standard of no more than 100 bacteria per utensil are listed as such and are also expressed as percentages of the total number of samples. Percentages based on a standard of 1,000 bacteria per utensil are presented in the same table. Perhaps the most important finding is that in only one of the eight groups of utensils, glasses washed by machine, do the samples which meet the 100 standard exceed 50 per cent of the total number studied. It is further noticed in the table that the machine washing of glasses and cups yields results which are far superior to those obtained by hand washing of the same utensils, the difference in each instance being highly significant. There is, on the other hand, no significant difference in the apparent effectiveness of machine and hand operations with either spoons or forks. When the 1,000 standard is used as a basis of comparison, the results are very similar. It is noted that the combined samples for machine washed spoons and forks which pass (74.9 per cent) are just significantly greater than the combined samples of the same utensils washed by hand (68.6 per cent). As a matter of fact, the combined passing average for all silverware (spoons and forks) washed by hand is greater by far than that of glasses and cups washed by hand. This difference is at least

TABLE 1

Forks	688	478	69.5	114	85	74.6	5.1	4.64	1.09

* The calculation of the standard error of the difference in percentages (S.E._{diff.}) is illustrated as follows for glasses:
$$S.E._{diff.} = \sqrt{\frac{15.4 \times 84.6}{1046} + \frac{15.4 \times 84.6}{131}} = 3.35\%$$
 where 15.4% is the total per cent passing, namely $(113 + 68) \div (1046 + 131)$ and 84.6% is the total per cent failing, namely $100\% - 15.4\%$. A ratio of Difference/S.E._{diff.} of 2 or more is generally regarded as statistically significant.

partially due to the special treatment which silverware received. It is of interest that in another study the machine washing of glasses was also revealed to be superior to hand washing of the same utensil, but that the bacterial quality of spoons and dishes washed by machine was found to be no better than that of those washed by hand.⁴ In summarizing the data in Table 1, apart from the generally poor conditions disclosed, it is obvious that machine washing of glasses and cups yields results definitely superior to hand washing. No such clear-cut difference appears for spoons and forks. The data on spoons and forks will be examined in greater detail subsequently.

A comparison of hand and machine washing is made in Table 2 on the basis of the standard of no more than 100 bacteria, with the data further broken down according to the types of establishment sampled. The findings include those from cafeterias, waiter service restaurants, luncheonettes, and bars. Those from open stands are omitted be-

cause the number of samples was too small to be statistically significant. When the machine and hand washing processes for glasses and cups in the first three types of establishments are compared, it is noted that significant differences again exist. The degree of significance, as noted in the final column, is less for each type of establishment, as would be expected, than for all establishments combined (Table 1), and also differs among the several types of establishments. The differences for both waiter service and luncheonette restaurants are both of clear-cut statistical significance, whereas those for cafeterias are just significant. The results of the washing of silverware by the two methods show the lack of significant differences previously indicated in Table 1, with the exception that in luncheonettes, machine washing apparently did produce a significantly higher passing percentage of spoons than did hand washing. When the quality of hand washing of the several types of utensils in each of the four types of

Forks	173	102	59.0 ± 3.74						

* 1.70 is the Standard Error of the value 12.9% computed as $\sqrt{(12.9) \times (87.1)/388}$. In general the true % may be regarded as falling somewhere within 2 S.E. of the obtained value.

establishments listed is compared, the major differences in Table 1 are again noted; i.e., in each instance, samples of spoons and forks passed more frequently than did those of glasses and cups.

It is also observed from the table that the overall picture of cafeterias is the poorest while that of bars apparently is the best of those establishments which wash by hand. Thus the standard of excellence of cups in bars is somewhat higher than that in any of the other types of restaurants, even though the total percentage of passed samples for bars is under 20. Likewise, the relative cleanliness of the silverware sampled in bars is, at first glance, surprising; both spoon and fork samples passed more times than they failed. These results, 54 per cent and 59 per cent respectively, are superior by far to any of those ob-

tained with silverware in the other types of establishments. It should be made clear, however, that the superior cleanliness of silverware and cups in bars probably is due to circumstances unrelated to dishwashing practice. It is the fortuitous coincidence of (1) a state law which compels all establishments serving liquor at retail to serve food as well, and (2) the technic used in our survey. Bars, as a result of the law, carry a stock of eating utensils even though most of them serve food only infrequently. This fact was not considered in the survey and as a result utensils were sampled which probably had not been used for some time. Such a procedure, as has been mentioned earlier, gives a misleadingly low estimate of the number of microorganisms present when the utensils were freshly dry. The

above conclusion is confirmed by the fact that the status of the bar glass, the commonly used bar utensil, is no better than that of the waiter service or luncheonette restaurant, being superior only to that of the cafeteria.

When findings for hand washed utensils in cafeterias, waiter service restaurants, and luncheonettes are compared it is seen that, although the passing percentage of both glasses and cups from cafeterias are lower than those of the other two types of restaurants, these differences are not significant. When the results with glasses and cups in each of these three types of restaurants are consolidated, however, that of cafeterias is found to be just significantly poorer than those of either of the other two. The passing percentages of spoons and forks from waiter service establishments seem to be just significantly better than those of the other two types but when the findings for spoons and forks are pooled the differences become definitely significant.

It is of interest when the findings for machine washed utensils are compared, that cafeterias generally still occupy the poorest position.

Further analyses were made of hand and machine washing of silverware in an attempt to ascertain causes for the apparent lack of superiority of machine

washing. The hand wash data (spoons and forks combined) were divided into two groups; in one were placed the findings obtained in restaurants which washed in baskets and rinsed in very hot water, and in the other those which used neither baskets nor an adequate sterilization technic. The corresponding machine wash data were broken down into three groups, one for single tank machines, another for double tank machines, and the third for the special silverware machine previously described under Technic. Too few samples of silverware for adequate analysis were obtained from counter type machines, which were found in only 12 luncheonettes and open stands. It is of interest, however, that 21 of 29 (72 per cent) samples of glasses and cups from these machines did pass. Likewise, triple tank machines which were found only in six waiter service establishments also yielded too few silverware samples to record, although here too glasses and cups combined yielded a fair passing percentage, 14 of 26 (56 per cent). A comparison of the findings is contained in Table 3.

The first point of interest in Table 3 is that only about 5 per cent (53 of 1,030) of samples of hand washed utensils were obtained from restaurants which had clearly complied with the present New

York City Sanitary Code. These few establishments use an approved rinsing technic and water at high enough temperature. It is also worthy of note that this small group of samples met the standard of 100 more frequently (47 per cent) than did the remaining large group (30 per cent). This difference is statistically just significant. The high temperature hand wash results are also definitely superior to those of the double tank machine.

The most interesting finding in the machine data is the indicated marked superiority of the special silverware machine, as shown by the high passing percentage (68), over the single tank machine (36 per cent) and the double tank machine (16 per cent). The results with the special silverware machine are also superior to those of the great majority of establishments which wash by hand but are not statistically better than those of the relatively few samples from establishments which wash by hand and rinse with water in the proper temperature range.

AN EXAMPLE OF SATISFACTORY MACHINE OPERATION

Some 79 establishments which use single tank machines, the most common type, were studied. The general average of results obtained from this type of machine was raised by the findings obtained in a chain of luncheonettes. This organization, which sells food at very moderate prices, has developed an exceptional technic not only in dishwashing practice but also in the general sanitary operation of its establishments. A single tank machine whose operation is uniform is used in each restaurant. The operation is as follows: A trayful of dishes is inserted into the machine, a tablespoonful of trisodium phosphate is spread over the dishes manually and a sliding door is closed, automatically locking the machine. The process is started by press-

ing a button and the utensils are automatically washed for 2 minutes and rinsed for 15 seconds. The machine automatically stops when this operation is completed and the door may then be opened. Silverware is soaked or pre-rinsed in a shallow well of water with detergent before it is placed in the machine. It should be noted that there is no automatic control of hot water temperature nor automatic addition of detergent. An adequate supply of hot water, however, is furnished by a local steam company. It should be mentioned in fairness to the dishwashing problems of other establishments that the menu in this chain is limited to sandwiches, soups, frankfurters, pies, cakes, fruit juices, coffee, and milk.

A special swab-rinse study of some ten restaurants of this chain was made to determine what a well ordered process could accomplish. Fifty-three swab-rinse samples of glasses, cups, and spoons were obtained. Counts of these samples in all instances were under 100 with some showing very few bacteria.

A machine in one of these restaurants was used by us for some special tests in which the water temperature was lowered. It was found that all the samples of cups, glasses, forks, and spoons rinsed at temperatures ranging from 84° to 140° F. complied with the bacterial standard. It might be concluded from this that water temperature is not a very critical item if the detergent and the duration of wash and rinse are adequate. Findings similar to these have been reported by Tiedeman,⁵ by Ward and Dack,⁶ and by others.

DISCUSSION

The state of dishwashing practice and accomplishment as found in this survey is, on the whole, dismal. These swab-rinse results, however, are apparently not much worse than those which were found in surveys carried out in several sections of the United States during a

corresponding period (1944 and 1945) by mobile laboratories of the U. S. Public Health Service.⁷ Thus, while we found that 303 of 1,985 (15.3 per cent) samples of cups and glasses passed the 100 bacteria per utensil standard, the U.S.P.H.S. found that only 3,894 of 14,664 (26.5 per cent) samples of the same utensils were satisfactory by the same standard. Likewise, we found that 598 of 1,672 (35.7 per cent) samples of forks and spoons met the standard and the U.S.P.H.S. found that 2,423 of 7,086 (34.3 per cent) samples of spoons passed in its surveys. It seems, therefore, that much must be done to improve the status of utensil washing in restaurants. There is good reason to believe that such improvement is entirely feasible.

AN ESTIMATE OF THE FUTURE USEFULNESS OF THE SWAB-RINSE TEST IN NEW YORK CITY

Our findings seem to indicate that in the presence of an effective dishwashing technic, the swab-rinse test usually yields a result which is in compliance with the standard of no more than 100 bacteria per utensil as advocated by the A.P.H.A. It can be stated generally that, when the dishwashing operation is visually satisfactory to an experienced inspector, the swab-rinse test usually yields a satisfactory count; when the practice is questionable, on the other hand, a satisfactory count may or may not be obtained; finally, when the practice is obviously poor, the count usually fails to meet with the standard.

CAUSES OF POOR MACHINE WASHING

The main defects in machines are in original design and in operation. Defects in design are difficult to rectify in existing models in which the fundamental design is inadequate. The effects of poor design, however, may be ameliorated if all that is needed is the addition of timing devices or tempera-

ture controls or the alteration of certain small parts. Operational technic can be improved by the educational efforts of properly trained inspectors. Some defects noted in the operation of counter type and single tank machines are listed.

Counter Type Machine—Three common defects were found in the operation of this type of machine. The rinse water rarely reached 180° F., the city water pressure was often inadequate, and the application of detergent was irregular. It was found that operators were reluctant to use very hot water even if it were obtainable because of the fear that they might burn their hands. Although most machines are equipped with semi-automatic detergent dispensers, it was noted that operation of these dispensers was often deficient and as a result the detergent well overflowed. The feeding of detergent was inconstant for this and other reasons. It should be reiterated that despite these deficiencies the swab-rinse findings from the twelve establishments which used counter types machines indicated fairly good operation.

Single Tank Machine—Poor results from this type of machine are usually caused by haphazard timing of the wash and rinse operation and the irregular addition of detergent. The operator of a single tank machine frequently determines the duration of the wash and rinse periods by manipulating a handle. Obviously at that time of the day when clean dishes are at a premium, the operation will be rushed.

SUMMARY OF DEFECTS

The following are the chief defects observed in operation or construction of machines during the survey:

1. Dishes are not scraped or prerinsed.
2. The time of washing and rinsing is insufficient to clean or sterilize the utensils.
3. Water pressure is insufficient in the absence of auxiliary pumping

4. The rate of dilution of water in the wash tank compartment by waste rinse water is often too great in single tank machines so that the detergent may be dissipated. The rate is insufficient in multiple tank machines so that too great an increase of bacteria and other organic material may occur.

5. The wash and rinse tanks in multiple tank machines are sometimes constructed so as to permit a flow of water from the wash tank to the rinse tank with consequent contamination of the rinse water.

6. Nozzles are often clogged with food and are not regularly cleaned. In certain sections of the city, where hard water is used, lime deposit also reduces nozzle efficiency.

7. There are insufficient or inadequate hot water facilities and lack of a proper booster heater, on the rinse water particularly.

8. Automatic detergent feeding devices frequently do not function properly either because they are not refilled when empty or because they have become clogged.

Defects similar to these have been reported by Andrews.⁸

CAUSES OF POOR HAND WASHING

The inferior quality of results obtained by the hand washing process, particularly as regards glasses and crockery, is not at all surprising when viewed in the light of field observations. This, perhaps, can best be illustrated by citation of some instances of poor practice. Thus, it was found that the common two compartment sink is very frequently not used in the intended manner. It is quite obvious that the second or rinsing and sterilizing compartment is either improperly used or not used at all. In the case of the three compartment sink, it was often found that the third or sterilizing compartment is not used as such but as a pot washing or glass washing sink. It was observed, likewise, that the sterilizing facility of the two compartment sink with an adjacent sterilizer often is used exclusively for the washing of silverware. Bars, it was found, usually have a two compartment sink with an adjacent sterilizer. The sterilizer as a rule is not used or else appears to be in

poor condition. Frequently, one of the two sink compartments is used to store bottled soda and ice cubes while the remaining one is used to wash glasses by merely plunging them into water, usually in the absence of soap or other detergent. Occasionally, an inverted brush is used. Detergent is usually employed once or twice a day after the glasses have become obviously dirty and sticky. This condition applies to the so-called better type as well as to the run-of-the-mill establishment.

There are several reasons why this improper or non-use of existing hand washing facilities is a very difficult practice to alter. Perhaps, the most important factor is the frequently itinerant status of dishwashing personnel, since dishwashing is usually not a permanent profession. Should the proprietor actually desire to do a good job, which is not always the case, he would have great difficulty because of the lack of understanding of proper dishwashing technic by his personnel and their aforementioned transient status. Another complicating factor is the normal occurrence of rush periods in restaurants when often, because of insufficient stock on hand, there is a greater demand for than supply of clean utensils. This condition frequently gives rise to a quick and careless cleaning operation with the occasional by-passing of the rinsing or sterilization operation or both.

Finally, it would appear that a much more extensive inspectorial supervision will be needed to police hand washing operations properly. In fact, the task of satisfactorily supervising the hand washing process in the approximately 15,000 restaurants in New York City which are estimated to be using it appears to be a well nigh impossible one.

RECOMMENDATIONS

It is the considered belief of the present authors, as a result of the foregoing observations on hand dishwashing,

that no great improvement in the quality of washed utensils will be obtained until a large majority of eating establishments have efficient mechanical or combination manual-mechanical utensil washing devices.

It is realized that this conclusion although logical is unquestionably radical, and also difficult to implement immediately. But as part of a long-range program, it seems both sound and feasible.

Assuming the validity of this conclusion that universal mechanical washing of dishes is necessary—how may it be implemented? There are two possible complementary approaches.

One would consist of investigations to correct existing defects in mechanical equipment. In many cases existing equipment can produce satisfactory results—if some alterations are made—or if it is used intelligently. In this connection, the existence of adequate hot water facilities for each type of machine is an important factor. It is almost needless to add that alert restaurant management is almost always ready to cooperate in such endeavors.

The second approach would be made via the permit system. Health departments in most cities require restaurants to obtain permits in order to operate. In the great majority of instances no attempt or only a minimal one is made to regulate the physical structure or other facilities of the restaurant when a permit is issued. If this practice were changed so that plans were submitted before any construction, installation, or alterations were undertaken, a health department could insist upon the provision of sufficient space, ample hot water supply, and other adequate facilities for the washing of dishes.

When a permit is first granted or an important alteration is to be made in an eating establishment the number of meals that can be served at peak periods based on the number of seats

available and the expected turnover time would be determined. This figure would indicate the number of eating utensils of the several kinds needed and the types and capacity of dishwashing equipment required to handle this maximum load. Presence of a sufficient quantity of dishes and silverware and of good dishwashing equipment of adequate capacity would eliminate or mitigate the rushing of the dishwashing operation during busy periods. The capacity of the hot water system, both as to temperature and volume, would also be determined as would the type of detergent and detergent dispenser to be used. Finally the number of persons needed to operate properly and supervise the dishwashing equipment would be established.

SUMMARY

A survey of dishwashing practice and performance was carried out in 1,005 restaurants in New York City. It was found that about 88 per cent of establishments used hand methods either entirely or in part and that 17.5 per cent used machine methods entirely or in part.

The quality of washing as measured by the swab-rinse test was found in general to be very poor. Evidence is presented which indicates that unsatisfactory conditions are not peculiar to New York but also exist in other sections of the country.

Hand washed glasses and cups met the bacterial standard of no more than 100 colonies per utensil in 10.5 per cent of instances (176 of 1,675 samples), whereas the analogous figure for the same utensils washed by machine was 35.8 per cent (509 of 1,421). This difference is a very significant one and in favor of machines. Yet it is evident that, since only about two-fifths of machine washed samples passed, much improvement is needed both in the design and in the operation of machines.

Hand washed spoons and forks were found to pass 35.8 per cent of instances (509 of 1,421). This percentage is higher than that for hand washed cups and glasses and is equal to that for machine washed spoons and forks, 35.4 per cent (89 of 251). It was observed that only about 5 per cent of silverware samples which were washed by hand came from establishments which actually made a serious attempt to sanitize these utensils properly. It is noteworthy that the findings with this small group of samples were about 50 per cent better than those from the remaining 96 per cent of samples, which came from establishments in which less care is exercised. Another small group of samples which had been washed by a special silverware machine yielded a passing percentage which was about twice as good as the general average for machine washing.

When the three main types of restaurants studied were compared, it was noted that both hand and machine washing in cafeterias was generally inferior to that in waiter service restaurants and in luncheonettes.

The obvious defects noted in both hand and machine operations are described in detail.

After evaluation, of the present and possible future status of hand washing, the conclusion seems justified that hope for satisfactory dishwashing practice lies in conversion to machine or manual-mechanical practice and the intelligent operation of this adequate equipment. The broad outlines of a program to implement this conclusion are described.

Critical Study of Machine Dishwashing*

W. L. MALLMANN, PH.D., F.A.P.H.A., PAUL DEKONING,
AND LEO ZAIKOWSKI

*Departments of Bacteriology and Public Health, and Mechanical Engineering,
Michigan State College, East Lansing, Mich.*

THERE is little question that improperly cleaned and sanitized dishes constitute a health hazard. There is no question that used dishes and silverware carry mouth microorganisms. Many mouth bacteria are carried on dishes and silverware. Mallmann and Devereux in 1935¹ examined beverage glasses for the presence of streptococci. In many cases where 5 glasses were examined in a tavern, 3 of the glasses, or 60 per cent, showed the presence of streptococci. Out of 15 glasses examined in one series of tests, 8 carried streptococci and one of these glasses carried hemolytic streptococci. The presence of mouth spirochetes was demonstrated by Lyons² who collected swab cultures from 200 used and clean glasses in eight taverns in two cities. In one tavern 8 out of 62 glasses when returned from the table carried *Borrelia vincentii*. In another establishment 3 out of 22 used glasses and 4 out of 20 supposedly washed and sanitized glasses carried this organism.

The fact that used beverage glasses carry streptococci and spirochetes, which are frequently pathogenic, is indicative of the presence of many other pathogenic bacteria and viruses. The washing of contaminated glasses in a com-

mon receptacle means the discharge of these organisms into the wash water and a redistribution of the organisms on all dishes washed in the same water.

Even though pathogenic bacteria and viruses were absent on used dishes and silverware, sanitization would still be necessary to reduce contamination hazards in the preparation and serving of foods. For example, it has always seemed absurd to demand a low count in milk and ice cream and then allow the dispenser to serve these foods in dishes laden with microorganisms.

There are little or no reliable data on the operation of mechanical dishwashers, both as to cleaning and sanitization. This is definitely attested to when codes are found throughout the country requiring 2 to 3 minutes' exposure to water at 170–180° F. for all dish sanitization irrespective of whether the work is done by hand or machine. The U. S. Public Health Service Code³ states: "Immersion at least 2 minutes in clean hot water at a temperature of, at least, 170° F. or ½ minute in boiling water." This statement applies only to hand-washed dishes. The Code further states: "In dishwashing machines the use of high wash water temperature, higher detergent concentrations, and the more efficient mechanical removal of soil make it possible to employ a shorter exposure period for final treatment."

Much of the confusion is perhaps due to the recognition of only one time and temperature without regard to the

* Presented before the Engineering Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 12, 1946.

NOTE: These studies were made possible through a grant from the National Sanitation Foundation and a loan of machines from the Dishwashing Machine Manufacturers.

method of procedure. Much confusion is also due to a lack of information upon necessary time and temperature in dishwashing machines. The U. S. Public Health Service Code states: "Additional research on dishwashing machines will be required definitely to establish the necessary wash and rinse temperatures, the minimum washing and rinsing time . . . the optimum concentrations of different detergents and similar factors. However, it seems to be fairly well established that the wash water temperature should be approximately 140° F."

This paper presents, in part, some phases of research in studies in mechanical dishwashing. A complete report will be presented later.*

STUDIES ON TIME AND TEMPERATURE OF RINSE

The first phase of our studies pertained to the time and temperature of rinse in mechanical dishwashing.

To measure the effectiveness of the rinse it was necessary to develop some method of holding test organisms on the test plates during the rinse period. Rinsing washes off most bacteria so that bacterial populations become so low they are insignificant and of no comparative value. Accordingly, the first problem was the development of a soil that would remain intact on the test plates throughout the rinse period and which still could be easily resuspended in sterile saline so that bacterial counts could be made to determine survival numbers. Many soils were tried. The final soil consisted of the following:

- 265 ml. distilled water
- 17 gm. corn starch flour
- 15 ml. test organism suspension
(standardized by photolometer)
- 10 ml. India ink

The ingredients were placed in a Waring blender and mixed for 2 min. to

produce a well mixed suspension which remained stable during the period of spraying on the test plates. Because it was impossible to sterilize the mixture without destroying its property to adhere to the test plates, the ingredients had to have low bacterial populations.

The soil was sprayed on 9 in. white China dinner plates by a specially devised soiling machine⁴ which places a definite quantity of soil on the plates in an even film. The plates were then placed in a drying cabinet at a temperature of 105° F. for 17 hrs. in the presence of calcium chloride.

The test organism for measuring effectiveness of time and temperature of rinse must have a heat-resistance equal to or greater than pathogenic bacteria which might be found on used dishes and silverware. The only established test organism having such resistance is a strain of *Escherichia coli* which has been used extensively for checking pasteurization temperatures. This strain was tested but was found to die rapidly from desiccation during the drying period of fixing the soil to the plates. Furthermore, because it was necessary to use unheated soils and because it was impossible to use aseptic conditions, it was necessary to use a test organism which would be easily identified on the agar plates. *Escherichia coli* could, of course, be readily identified on special diagnostic media but, due to the attenuation of the organisms as a result of desiccation and heating, such selective media would not allow the growth of many viable cells. Strains of *Staphylococcus aureus* were tried but also could not withstand desiccation. A chromogenic coccus, *Micrococcus caseolyticus* was finally selected because it gave a yellow colony on agar and because it withstood desiccation fairly well.

This organism has good heat resistance. Its comparative heat resistance to that of other test organisms is pre-

* A research bulletin is being prepared. This will be published by the National Sanitation Foundation.

sented in Table 1. The thermal death points were made by use of the organism-impregnated glass rods, similar to those used in the Use-dilution technic for measuring disinfectants.⁵ In this technic glass rods 1 in. long and $\frac{1}{4}$ in. in diameter, with a small glass loop at one end for handling, are dipped into a 24 hr. broth culture of the organism and allowed to dry on sterile filter paper in Petri dishes. Care must be exercised in placing the rods on the filter paper. Rolling will remove many organisms. The rods are allowed to dry for 30 min. at room temperature to fix the organisms on the glass surface. Sterile water was placed in disinfectant medication pots in 10 ml. quantities. The medication pots were placed in a constant temperature water bath. The glass rods held on a platinum wire were lowered into the water bath for intervals of 10 and 15 sec. and then immediately dropped into 10 ml. F.D.A. broth in test tubes. All tubes were incubated at 37° C. for 48 hrs. *M. caseolyticus* was found to have a thermal death point of 158° F. in 15 sec. *E. coli* had a thermal death point of 156° F. in 15 sec. and *S. aureus*, 154° F. at 15 sec. *S. fecalis* had the same thermal death point as that of *M. caseolyticus*. Dahlberg⁶ found the thermal death point of *M. tuberculosis* to be 160° F. at 5 sec. This is comparable to that of *M. caseolyticus*. The stability of *M. caseolyticus* toward heat is shown in Table 2. Over a period of approximately 9 months the heat resistance remained fairly constant.

The data show that this organism can be used as a test organism for measuring heat sanitization.

TABLE 2

The Heat-resistance of *M. caseolyticus* over a Period of 9 Months Tested by Capillary Tube Method of Determining Thermal Death Points Expressed in Degrees F.

Date of Testing	Exposure in Seconds		
	5	10	15
Dec. 7, 1945	—	156°	154°
Feb. 26, 1946	—	158°	156°
April 9, 1946	—	158°	156°
Sept. 7, 1946	160°	156°	154°
Sept. 22, 1946	158°	156°	154°

The thermal death point determinations, using either the capillary tube or the Use-dilution rod method, are made on unprotected cells, that is, cells which are not surrounded by a protective coating of foreign material. In the tests made in the dishwashing machines the organisms are purposely covered with a protective coating of corn starch to hold them on the test plate during the period of the rinse. Some organisms on the surface of the film coating are lost by mechanical removal but most of them are retained. To check the effect of the film-coating on the cells, microscope slides were sprayed with the soil containing *M. caseolyticus* on one side in the same manner as the test plates. The slides were then dried at 105° F. for 17 hrs., when they were dipped into a constant temperature water bath at temperatures of 130°, 150°, and 170° F. for intervals of 10, 20, 30, and 40

sec. After exposure, the film-coating was removed with a sterile swab and the material was suspended in sterile saline and plated on tryptose glucose extract agar. After 48 hrs. incubation the number of viable organisms on each slide was determined. The data are presented in Table 3. It will be observed that complete kill was not obtained in 10 sec. exposure at 170° F. When the organisms were checked with the Use-dilution rod method, complete kill was obtained at 160° F. in 10 sec. This shows that the film-coating protected the organism to a marked degree against the lethal action of the heat. It will be observed, however, that the percentage reduction was 97.9 at 170° F. in 10 sec. The 10 degree increase in temperature over that of the glass slide method thus serves as a safety factor in the calculation of proper time and temperature of the rinse so that there is full assurance that a 99 per cent kill in the rinse chamber of the dishwashing machine can be accepted as an index of public health safety. Furthermore the fact that 99 per cent can be killed at a given time and temperature is an assurance that bacteria would be killed even though a dish were not thoroughly washed.

dishes could be washed in one and rinsed in the other.

Controls were placed on hot water lines in such a manner that constant temperature could be delivered to the machine throughout the experiments. Recording thermometers were used so that a record was kept of the temperature during each experiment. Timing was done by stopwatch control. Flow pressures of the water were held constant so that rinse action would be as nearly comparable as possible for all machines.

In testing each machine, test plates were arranged in the wash racks with two plates in the front row, labelled No. 1 in front-right and No. 2 in left front position. Two plates were placed in the center of the rack, labelled No. 3—front center and No. 4—back center. Two plates were placed in the back row, labelled No. 5—back left and No. 6—back right. In the studies presented, all plates were slanted with the face up. This was done to avoid soil removal patterns caused by interference from the support rods in the rack.

The results obtained at 170° F. for 5 and 10 sec. intervals of exposure are presented in Table 4. The average percentage kill at 5 sec. exposure for all

The studies on dishwashing machines were made on manufacturers' models. The machines used were all single tank hand operated machines. Two machines of each manufacturer were placed in tandem with a table between so that

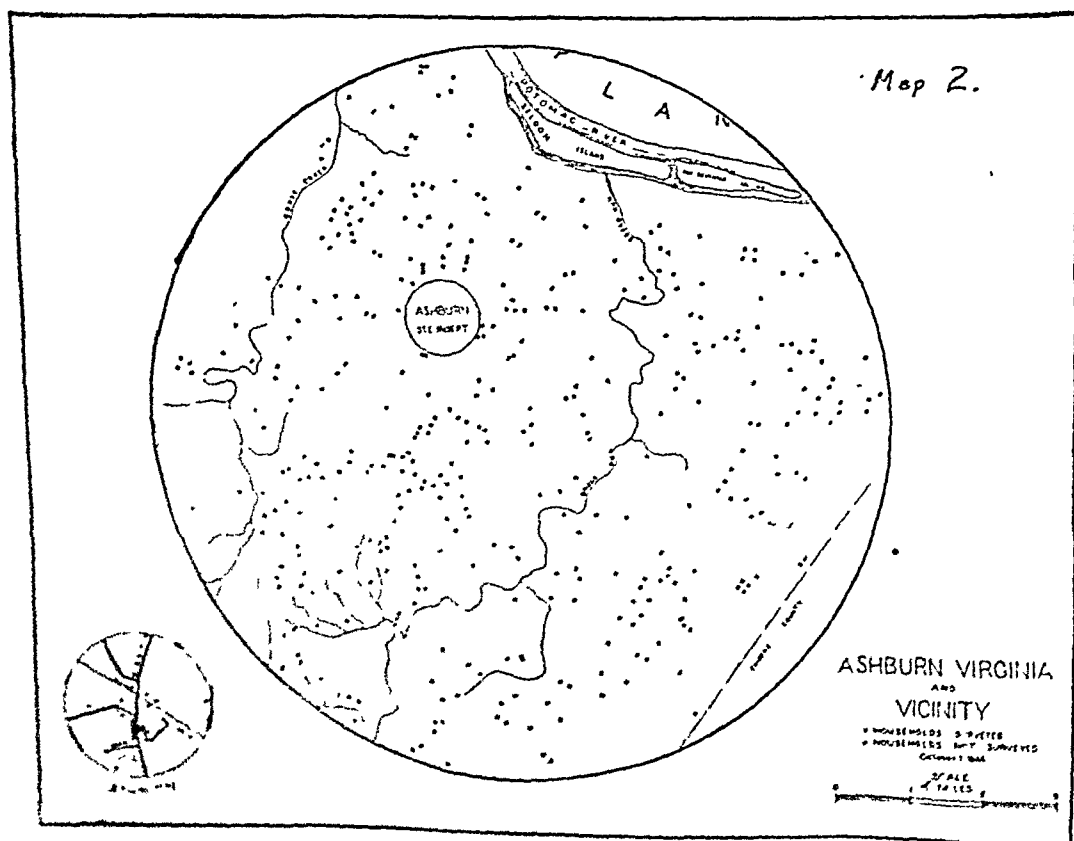

machines was 92.17, and the range among the machines was from 88.55 to 98.80. With a 10 sec. exposure a percentage kill of 99.51 was obtained with a range among the machines from 99.11 to 99.81. The data from one machine

the sire of 8 pups born in January, 1945. The 2 year old mate has remained healthy. Two female pups of this litter were destroyed at birth; one male died when 1 week old of unknown cause; one female was healthy when destroyed in February, 1946, after giving birth to 9 pups, only one of which has been ill, and careful examination has produced no evidence of histoplasmosis; one male of the original litter died in April, 1946, with symptoms suggestive of histoplasmosis; 2 females died in May, one with proved histoplasmosis and the other with suspicious symptoms; and one male died on July 19 with proved histoplasmosis. This animal was referred for study to Dr. M. Parsons of Arlington, Va. The two dogs dying with symptoms suggestive of histoplasmosis had anorexia and emaciation; no definite diagnosis was established as no material was available for examination. In the three dogs dying

of proved histoplasmosis the diagnosis was established by recovery of *Histoplasma capsulatum* from cultures of the spleen and other organs.

The case of the male dog dying of histoplasmosis on July 19 will be the subject of a later report, but a few notes will be included here. Ticks, *Dermacentor variabilis*, were fed on the dog during illness and *Histoplasma capsulatum* was recovered by culture from a ground-up tick soon after feeding. This was not surprising inasmuch as repeated blood cultures showed a heavy infection. Further studies of the relation of ticks to histoplasmosis are under way. On July 2 and again on July 10, two pairs of healthy dogs were placed and remained in continuous contact in the same cage with the naturally infected dog dying on July 19. None of these four contacts has shown any evidence of histoplasmosis to date.

Map 1 shows the location of the two

country estates where the infected dogs were kept. They were valuable dogs which were carefully fed and cared for. They were not used for hunting. There were 11 other dogs on one estate, 5 old coon hounds and 6 pups; all have remained well except two which were studied without evidence of histoplasmosis being found. Only one person was found on these estates with an illness suggestive of histoplasmosis; thorough hospital study gave no evidence of *Histoplasma* infection. No evidence of any contact whatsoever could be found between proved canine and human cases of histoplasmosis.

The household studies and physicians' reports yielded several cases of illness in which clinical and laboratory studies produced various diagnoses but no evidence of histoplasmosis. To date,

476 white persons in the vicinity of Ashburn have been satisfactorily x-rayed and skin-tested with histoplasmin and tuberculin (PPD), and their medical histories have been completed. Map 2 shows the geographic distribution of households studied.

Table 2 shows the number of persons having (A) calcified pulmonary lesions, (B) positive skin reactions with histoplasmin, and (C) positive skin reactions with tuberculin (PPD). The histoplasmin reactions are those of initial clinic visits; retests are described later. A tabulation similar to Table 2 has been made showing the presence or absence of calcified pulmonary lesions and the reactions to histoplasmin and tuberculin according to the medical histories of persons tested with respect to pertussis, diphtheria, scarlet fever, pneu-

"P" = The probability that differences in percentages as great or greater than shown would occur in independent attributes through chance sampling variation.

monia, illness with diarrhea, ascariasis, and malaria. This tabulation shows no significant association between these diseases and pulmonary calcification, and no association with the histoplasmin or tuberculin skin reaction.

Column A of Table 2 shows that 41.2 per cent of the group studied had calcified pulmonary lesions. This was relatively constant in all age groups except 1-5 years where, as expected, it is lower. It is significant that recent residents of Loudoun County are not as apt to have calcified pulmonary lesions as residents of 3 years or longer. Also, individuals with a history of tuberculosis or of having lived in the same household as a person with a history of tuberculosis appear more apt to have calcified pulmonary lesions than individuals without this history. Column A shows no significant association between pulmonary calcification and either sex or the tuberculin reaction.

In the area studied it was impossible to demonstrate any direct association between the occurrence of pulmonary calcification and positive histoplasmin skin reactions. From the crude data in column A one might suspect that if a larger sample were taken a significant association would have been shown. Therefore, the following analysis of the data seems pertinent particularly in view of the association between these attributes reported in other areas.^{1-3, 7} The number of persons having pulmonary calcification according to the histoplasmin and tuberculin skin reactions were:

		Per cent
Histoplasmin-positive	Tuberculin-positive	48/102 47
Histoplasmin-positive	Tuberculin-negative	122/291 42
Histoplasmin-negative	Tuberculin-positive	5/12 42
Histoplasmin-negative	Tuberculin-negative	21/71 30
Total		166/476 41

The differences in the above percentages might well be expected by chance sampling variation alone. This suggests that the small difference shown in column A was not due to direct association between the histoplasmin reaction and pulmonary calcification. Thus among the group having pulmonary calcification a comparison of persons positive to both histoplasmin and tuberculin with persons negative to histoplasmin and tuberculin showed that the former included a disproportionate excess of persons who were in the older age group, who resided in Loudoun County 3 years or longer, and who had a history of either having tuberculosis or living in a household with a person with tuberculosis. These three attributes were definitely associated with the occurrence of pulmonary calcification; the first two were associated with the occurrence of positive histoplasmin reactions, and all were associated in the direction that could produce differences similar to those shown above in the percentage of persons with calcified pulmonary lesions, but independent of the histoplasmin reaction. Hence it would appear unlikely that a larger sample, taken from this area where recent, proved cases of human histoplasmosis occurred, would demonstrate any direct association between the occurrence of pulmonary calcification and positive histoplasmin skin reactions.

Column B of Table 2 shows that 82.6 per cent of the group had a positive reaction to the histoplasmin skin test. The incidence of positive reactors is high in all age groups, being 47 per cent in the group 1-5 years old and more than 80 per cent in the older age groups. As with pulmonary calcification, recent residents of Loudoun County are not as apt to have a positive histoplasmin reaction as residents of 3 years or longer. There may be some association between persons reacting to the histo-

SIZE OF HISTOPLASMIN REACTION ACCORDING TO AGE, SEX,
AND RESIDENCE IN LOUDOUN COUNTY

INITIAL SKIN TEST IN 476 WHITE PERSONS

plasmin test and those reacting to the tuberculin test. As with pulmonary calcification, the histoplasmin reaction was not significantly associated with sex.

Column C shows that 24.4 per cent of the group gave a positive reaction to the tuberculin (PPD) test. There is a progressive increase with age in the proportion of persons reacting to tuberculin, and males were more apt to be positive reactors than females, other-

wise no significant association was found except as mentioned above.

Chart 1 shows the relation between the size of the histoplasmin reaction and age. The chart was prepared to determine whether it would indicate a better criterion for classifying histoplasmin reactions as positive (5 mm. or more diameter of edema was classified as positive). No better criterion was evident.

Three to 8 months after initial test,

40 persons with negative initial histoplasmin skin tests were retested, again x-rayed, and their medical histories including an interim history were carefully checked and studied. Fifty-eight persons with positive initial histoplasmin tests were likewise retested, again x-rayed, and studied medically. Of the 58 persons initially histoplasmin-positive, 24 (41 per cent) had pulmonary calcification; on retest 54 (93 per cent) remained histoplasmin-positive, and of these, 24 (44 per cent) had pulmonary calcification. Of the 40 initially histoplasmin-negative, 20 (50 per cent) had pulmonary calcification; on retest 22 (55 per cent) became histoplasmin-positive, and of these, 9 (41 per cent) had pulmonary calcification. The serial x-ray films of all individuals retested were carefully studied and not a single change was detected between initial and last test. From the medical interviews no evidence of illness could be elicited that could be associated with a change in the histoplasmin skin reaction.

SUMMARY AND CONCLUSIONS

In September, 1945, when the fourth human case of histoplasmosis (all fatal) was recognized among the 20,000 population of Loudoun County, Virginia, the authors began an intensive search for evidence of infection in man and animals. Local physicians, nurses, veterinarians, and others were interested in the problem and they reported cases of suspicious illness in man and animals to the authors for clinical, mycological, and pathological study.

Eight hundred and eighty-six animals have been captured and studied, and among these, only one rodent (*Mus musculus*) and one dog have been found naturally infected with histoplasmosis. Two other dogs of the same kennel have been found naturally infected in Loudoun County and reported.¹²

All infected dogs were associated

with each other and the infected rodent was captured in the basement of the home where the dogs which were later proved infected had been kept some 19 months previously. The animal and human cases were distant from each other and no contact between them could be established.

Some 500 persons residing in the area where recent proved infection with *Histoplasma* has occurred, have been studied and to date no evidence of human infection was found. Of the 476 white persons surveyed, 83 per cent had a positive histoplasmin skin reaction at initial test, and 41 per cent had calcified pulmonary lesions. Persons who were histoplasmin-positive were older and had resided in Loudoun County longer than persons who were negative. Persons who had calcified pulmonary lesions were older, had resided in Loudoun County longer, and were more apt to have a history of tuberculosis or to have household association with a person having a history of tuberculosis than persons with no calcified pulmonary lesions. No direct association could be established between the occurrence of positive histoplasmin skin reactions and pulmonary calcifications.

Forty persons initially histoplasmin-negative and 58 persons initially histoplasmin-positive were retested 3 to 8 months after initial test. On retest 7 per cent of the positives became negative, but 55 per cent of the negatives became positive. In all, the individual serial chest x-rays showed no change, and repeated medical studies gave no evidence of any suspicious illness either prior to or during the period of change in skin reaction.

To date no evidence of mild human histoplasmosis has been found in Loudoun County, Va.

ACKNOWLEDGMENT: This study was made possible through the complete coöperation of the people of Loudoun County. Mrs. Tillie Monroe, principal of the Ashburn School, the

Parent-Teacher Association, and other citizens of the community have facilitated the study in every possible way. The physicians of Loudoun County, especially Drs. J. A. Gibson, J. T. Jackson, and G. H. Musgrave, have given every assistance. The Virginia State Health Department and the Loudoun County Health Department coöperated in the study and furnished nurses, technicians, and x-ray equipment for the clinics.

THE CONTROL OF AIR-BORNE INFECTIONS

WHEN any new procedures are introduced in public health, we must expect a swing of the pendulum between extremes of enthusiastic acceptance and of cautious negation. Recent suggestions with regard to the disinfection of air by ultra-violet irradiation or by the use of aerosols and the reduction of atmospheric pollution by control of dust form no exception to the rule.

Since the subject was discussed in these columns on an earlier occasion,¹ the pendulum has been swinging toward the side of a not unwholesome scepticism, as presented in two reports published in an earlier number of this JOURNAL. With the Special Review Article, which opens the present issue, the time seems ripe for a review of recent trends of thinking in Aero-Epidemiology.

The first of the articles in question was the Report of the Subcommittee for the Evaluation of the Control of Air-borne Infections of our Association Committee on Research and Standards, under the chairmanship of J. E. Perkins.² This report deals particularly with the control of the spread of disease by droplet nuclei and air-borne dust, considering "droplets," as distinct from "droplet nuclei," to be a form of direct contact infection. It points out that the value of control of secondary infections by irradiation in operating rooms has been impressively demonstrated; that striking results have been reported as to control of communicable diseases in contagious pavilions and pediatric wards; that irradiation of the upper air of schoolrooms in Swarthmore and Germantown, Pa., apparently controlled two epidemics of measles and showed beneficial results in a epidemic of chicken pox. Mumps, which prevailed at a time when relatively high humidity existed (under which conditions ultra-violet light is least efficient) showed less clear results. At Camp Sampson, a group of naval personnel protected by irradiation showed a 25 per cent lower incidence of "respiratory admissions" than did a control group. There seems no reason to doubt that the use of glycol vapors, in aerosol form, might produce similar results; but no similar controlled epidemiological investigations have been made with these disinfectants.

The major conclusions of this report may be summarized as follows:

"The oiling of floors, blankets, and bedding has now developed to the point of practical application in the suppression of dust. Such measures constitute good

housekeeping. They reduce bacterial contamination of the air, but there is as yet insufficient evidence that they prevent disease.

"The available evidence strongly indicates that methods of air disinfection (ventilation, ultra-violet irradiation, and glycol vapors) are useful adjuvants to aseptic techniques in the reduction or elimination of air-borne infections in operating rooms and in contagious disease and pediatric wards.

"The general use of ultra-violet irradiation or disinfectant vapors in schools, barracks, and in specialized industrial environments is not justified at the present time. There is great need for further carefully controlled field studies to define the mechanisms of the spread of infectious disease among these types of populations.

"There is no justification for the indiscriminate use of ultra-violet light or other methods for disinfecting air in homes, offices, or places of public congregation."

A second important review was presented by the Committee on Sanitary Engineering of the National Research Council under the chairmanship of Abel Wolman.³ This report first discussed somewhat inconclusive results on dust suppression by oiling at Fort Bragg and elsewhere; and much more striking results obtained in the British and Canadian armies. The British studies showed a rate for respiratory disease incidence of 7 per 1,000 in barracks where the floors were oiled as compared with a control figure of 38 per 1,000; and the Canadian data led to the mandatory oiling of floors in all Canadian army buildings. So far as irradiation is concerned, the Camp Sampson results are cited in some detail. In all these experiments, laboratory tests and tests for beta-hemolytic streptococci showed a marked decrease in air contamination. With regard to disinfection by the use of glycol vapors, similar reductions in bacterial content have been reported; but data on actual decrease of disease by this procedure in American and Canadian barracks and at the Lockheed Air-Craft plant were much less significant than in the case of irradiation. The committee concludes that "the oiling of floors and blankets and, in hospital wards, of sheets and pillow cases, has been shown to be a practical, cheap, and effective measure"; and feels that this procedure should be employed either with or without means for air disinfection. As to disinfection by irradiation or by glycol vapors, it is concluded that these procedures "may have a measurable effect upon the attack rate from certain respiratory diseases, but experience is not sufficient to justify drawing definite conclusions." The committee, therefore, "does not recommend the general use of these disinfecting devices for the present. Much research and development work by qualified persons remains to be done."

All observers seem to be agreed on the value of dust suppression in such places as barracks and hospitals. As to the relative importance of air-borne dust as compared with droplet nuclei it is of interest to note that Hare and Mackenzie from Toronto⁴ have recently stressed the former, although their arguments do not seem too convincing. Oiling is, however, a cheap and easy procedure and requires none of the special precautions involved in air disinfection. The details of this procedure are discussed by C. G. Loosli in our Special Review Article this month.⁵ He cites certain of the studies discussed in the reports already reviewed, and particularly the very striking results obtained in a British measles ward where cross-infection rates (using Group 1, type 6 streptococci as an index) were cut from 73 per cent to 19 per cent and complication rates from 14 per cent to 3 per cent by oiling floors, bed clothes, garments, and all other cotton and woolen

fabrics. The oiling technique (for hospitals and barracks) may be considered to have "arrived."

Air disinfection may also be considered to have "arrived" as a procedure which is certainly advisable in the operating room and highly desirable in the contagious disease pavilion and the pediatric ward. Its extension beyond this point is, at present, still problematical; and nothing could do more to prejudice sound progress than commercial over-exploitation of such procedures. Dr. R. E. Dyer, Director of the National Institute of Health issued on January 5, 1947, a salutary warning in this regard. He said, "During the past few months, several articles have appeared in the public press relative to the possible efficacy of glycol vapors and ultra-violet radiation in reducing certain infectious diseases, particularly upper respiratory diseases, such as the common cold. Due to the fact that many inquiries have been made as to the possibility of using one or both of these methods in public buildings, it is felt that a statement at this time should be made concerning the use of such installations.

"Committees of the National Research Council and the American Public Health Association have studied and reviewed the data on such installations. Within the past several weeks, these two committees separately have submitted reports. Both of these committees feel that the use of either glycol vapors or ultra-violet radiation is still purely in the experimental state and that the data collected so far do not warrant the installation of such equipment in public buildings and industry in the hope of cutting down upper respiratory infection. The U. S. Public Health Service, through its research organization, the National Institute of Health, has conducted rather extensive studies on both glycol vapors and ultra-violet radiation and fully concurs in the reports and recommendations made by the committees of the National Research Council and the American Public Health Association. It must be emphasized that direct unshielded ultra-violet radiation of sufficient intensity to kill microorganisms in the air is also harmful to the eyes and exposed skin of humans. These observations are not intended to indicate that the future will or will not disclose new public health values in the application of either glycols or ultra-violet radiation. Much experimentation is needed, however, before a decision can be made as to whether such application may or may not be warranted."

It is not to be assumed that recent studies have in any sense negated the value of air disinfection. They have merely emphasized the importance of caution in urging processes whose real field of usefulness has yet to be determined. That these procedures do reduce the microbic content of the air is certain; and they can be utilized, with appropriate precautions, without danger. As Loosli concludes, "the magnitude of the problem of the control of air- and dust-borne diseases has been emphasized recently by Mudd.⁶ The employment of these dust-laying procedures in conjunction with other methods of air disinfection, such as glycol vapors, ultra-violet light, and adequate ventilation, offer the best opportunity for their control."

The problem is a quantitative one. "How great a reduction in disease incidence may a given procedure, applied in a given indoor space be expected to produce?" It should be remembered that even a small percentage reduction may be of major importance, if the percentage is applied to a high initial incidence. A 25 per cent reduction in the incidence of common colds would mean more for the public health than a 90 per cent reduction in the incidence of measles or mumps.

The answer to this question will obviously vary with the kind of space in which air disinfection is applied. In the hospital ward, air disinfection affects the patient for 24 hours a day and other sources of possible infection are reduced to a very minor hazard. Here, the case is reasonably clear.

A second group of problems is presented by the barracks and the school. In barracks we have close aggregation of large numbers for most of the indoor life of the individual; in schools and in certain industrial establishments, the same condition obtains for a more limited time period. It is significant to note that Wells's early studies in the schools near Philadelphia showed good results in measles and chicken pox (spread chiefly from child to child) but not for the common cold (where spread among the adults in the community plays so large a part in transmitting disease to children as to swamp any beneficial result of schoolroom disinfection). One might differ from Perkins's committee which apparently drops places of public assemblage from the intermediate class to those where there is no reasonable possibility of a useful application. (He is safeguarded by the term "indiscriminate"; since there is no value in "indiscriminate use" of any procedure anywhere.) The very close aggregation of a very large number of persons—even for a short space of time—may be a significant health hazard. On the other hand, we must agree with the Perkins committee in excluding the disinfection of air in homes and offices (except perhaps large and crowded offices) from the area of probable, or even possible usefulness. Aggregations are commonly so slight and other opportunities of infection so great in the home and the office as to make fruitful results most improbable.

The barracks, the school, the large industrial shop, and the large office seem to offer the area of greatest possible promise. It is here that we need serious and well controlled and long-continued experimental study, such as is now being conducted in schools in New York State and elsewhere; and a preliminary report from New York will be published in the May issue of this JOURNAL.

We should be cautious and critical, as Dr. Dyer has emphasized; but we should also be patient and open-minded. The upper respiratory infections constitute our major problem of communicable disease control in the Temperate Zone; and any procedure which can affect their incidence would represent a significant advance in public health.

A CABINET POST OF HEALTH, EDUCATION AND SECURITY

THE introduction into the Congress by Senators Fulbright and Taft and Representative Harris of a bill for the establishment of a new executive department of the federal government to cover the fields of Health, Education and Security

promises to be an important milestone in the history of public health in the United States.

For nearly a century and a half our national health service was under the Secretary of the Treasury—a historical accident due to the fact that this branch of our government was originally the Marine Hospital Service, established to provide funds for hospital care for sick sailors stranded in strange ports. As the scope of its work enlarged, it became the "Public Health and Marine Hospital Service" and the "United States Public Health Service," but still remained under the Treasury. The plan actually worked well, since the Secretary of the Treasury was generally one of the most influential members of the Cabinet and gave excellent support to the Surgeon-General of the Service under his aegis. The allocation was, however, clearly one which could not be defended on logical lines; and in 1939, under the President's emergency power, the Public Health Service was transferred—with the closely related services of the government dealing with education and social security—to the Federal Security Agency where it has continued to operate with success and to benefit by closer connection with allied federal functions.

The new bill (S. 140 and HR 573), in essence, raises the temporary Federal Security Agency to permanent Cabinet status, by providing for a Secretary of Health, Education and Security with under-secretaries, representing each of the three divisions implied in the title of the Cabinet officer.

The three under-secretaries must be qualified experts in their respective fields; and the Children's Bureau is left under the Under-Secretary for Security. The plan includes provision for advisory committees of experts in various fields; and states that the objectives of the department shall be attained so far as possible through state and local agencies, public and voluntary, so as to protect local independence and autonomy. The Committee for the Nation's Health objects to the sharp definition of the three bureaus, to the appointment of under-secretaries who are professional experts, and to the emphasis on decentralization.

Many more conservative physicians are dubious about the bill on almost exactly opposite grounds. The A.M.A. has repeatedly urged a separate Department of Health, with a physician in the Cabinet. The *Journal of the A.M.A.*¹ points out—with apparent disapproval—that the bill does not specify that the new Secretary shall be a physician (or an educator, or an expert in Social Security). This criticism seems wholly unjustified to anyone familiar with the basic principles of our federal government. According to the spirit and practice of American democracy, the Cabinet officers of the national government are political appointees, members of the official family of the President. They represent the party in power. The actual conduct of the department is in the hands of the civil servant who is its permanent head; and the duty of the Cabinet officer is to represent that permanent expert and translate his technical objectives into political reality. This is an altogether sound policy. If the temporary Cabinet officer considered himself an expert, there would be grave danger of interference with the permanent civil service head who should determine technical aims and procedures. The proposed bill actually takes a step in this direction by providing that the Under-Secretary of Health must be a physician. There may be some question as to the wisdom of this provision; but if it is included, it should perhaps be specified that the post should be filled by a physician "qualified in the field of public health."

A second criticism has been made of this bill on the ground that it is

undesirable to combine the three functions of health, welfare, and education under a single Cabinet officer. Many enthusiasts (but not generally including experienced public health experts) have clamored for a Secretary of Health of Cabinet rank. Such a position is, however, somewhat unrealistic. It would obviously require the establishment of three new Cabinet positions to represent the three separate fields involved—a consummation which is highly improbable. It would in practice involve the appointment of a political doctor (or the President's family physician) as Secretary of Health and such an appointee would not be a very influential member of the Cabinet. The combination of the three fields, on the other hand, should provide a post of sufficient importance to attract a really first class leader and one who would carry weight in Cabinet counsels. Finally, the interrelationship between health, education, and security is an increasingly close one and the correlations effected in the Federal Security Agency have been of substantial value. The provision of an Under-Secretary for Health should give ample protection to our own special interests; and the program as a whole seems statesmanlike and sound.

No legislation is perfect and there may be important details in which the present draft should be modified. It would perhaps be desirable to reduce the bill to more general terms and leave details to administrative adjustment. Possibly the bill introduced by Senator Aiken (S. 712) provides the best simplified pattern. In general, however, the objectives of the bill seem admirable and represent the result of much careful consideration by thoughtful students of the problem. It follows a sound middle line between one extreme view which would insist on complete autonomy for health in a separate department under a political "medico"; and another extreme point of view, which would throw health and all other related activities into a large department without even the protection of an Under-Secretary. In any case, suitable amendment—and not rejection—of this measure should be in order. Perhaps the best solution would be the adoption of the Aiken substitute, which accomplishes the same ultimate ends in a simpler fashion.

It is of some interest to note that one of the most distinguished of American surgeons long ago visualized the objectives of this bill. In the book which so many of us are reading with keen pleasure this spring² is a letter to President Roosevelt under date of November 10, 1934, in which Harvey Cushing says: "Would it not be a good move just at this time to take into consideration the establishment—if not of a governmental department—at least of a super-bureau of public health to coördinate a number of welfare agencies? Such a department would naturally include such scattered interests as infant welfare and the Children's Bureau, old age insurance, possibly the matter of the veterans' hospitals and health compensation, vital statistics, the administration of the Food and Drugs Act, and the existent public health and Marine hospital service."

Thus, Cushing, more than twelve years ago, outlined the essential objectives of the Fulbright-Taft-Harris bill.

ARE OUR HEALTH DEFENSES CRUMBLING?

THE public health program of the United States has made an astounding record during the past fifty years; and that record is primarily due to a gallant

and devoted band of professional public health workers, the troops who have held—and continually advanced—the front line of the war against disease. Our ten schools of public health are organizing more effectively year by year in order to fill the ranks of leadership with even better qualified personnel. Yet disquieting news comes from the front. Boards of health and health officers are clamoring for more workers; but instead of new recruits they face in many instances serious depletion of their present staffs.

The reason for this is simple and obvious. It lies in the fact that while the cost of living and the income of manual workers is going up, the salaries of professional workers have remained static. They are not in this business for money. They are in it because they love their work. They will stand the situation as long as they can. Yet they have their own futures and often that of their families to consider; and in many cases they are ultimately forced to seek some more remunerative vocation than public health.

What such a situation may mean is clearly indicated by what is now happening in the educational field.

"All Buffalo public schools are closed because of the teachers' strike."

"Norwalk schools delayed in opening because of teachers' strike for higher pay."

"Teachers' strike in Jersey town in demand for \$500 pay increase."

"St. Paul schools still closed because of teachers' strike."

"Twelve major school strikes have taken place since September—and many more are being threatened."

"Every state in the Union reports a shortage of qualified teachers."

"One out of every seven teachers is serving on a sub-standard certificate."

"Seventy-thousand teaching positions are unfilled because of the inability of communities to get the necessary teachers."

"Tens of thousands of classes are overcrowded."

These are the headlines of storm damage that are daily coming over the airwaves, in the winter of 1946-1947.

Is this a sudden outburst of temper, disloyalty, acquisitiveness, or other vices from which teachers, and indeed other public servants, are expected by profession and instinct to be free? No, it is a storm that has been breaking for a decade, the warning signals of which were ignored with a reckless disregard of the fateful consequences.

Such a storm has not yet broken in the public health profession—a profession with traditionally the same selfless and idealistic standards of service that have been the tradition of the teaching profession. But here too the storm signals are up. Here too unless the lightning rods are modernized, the leaking roofs reshingled, the sagging levees sandbagged, the coming storm will leave a similar wreckage the consequences of which will be as fateful and as far reaching.

Let us consider the situation in public health nursing. Careful budgetary studies made by voluntary nursing organizations in the New England States have clearly shown that the minimum beginning salary for a public health nurse—in order that she may live decently and meet her professional obligations—must be from \$2,200 to \$2,400, corresponding to the wage of a skilled factory operative. Yet in a survey made in 1945 by the National Organization for Public Health Nursing, it appeared that of 4,000 staff nurses employed by state, county, and city health departments, nearly a third received less than \$1,800 a year, and more than half less than \$2,040. In April, 1946, the salary scale for state health department staff nurses was \$1,500-\$2,160 in North Carolina and \$1,200-\$2,130 in South Carolina.

The situation is by no means limited to nurses. Recent data collected by our Association show that eight states establish a minimum beginning salary of less than \$3,000 for physicians, while similar beginning salaries are less than \$4,000 in twenty-five more states. Yet for physicians trained in public health work, positions under \$6,000 per annum are, at present, not attractive to those who are available and many, even of these now in positions that pay \$6,000 and more, are searching for, and finding better jobs or going into private practice. The physician in public health cannot be blamed for making comparisons between his annual income and the lucrative opportunities in the practice of medicine.

Good sanitary engineers too, are restless under present limitations, and there is no reason why they should not be, when industry and other non-public service offer so much better compensation. And so it goes with workers representing other professions in the health department—the specialists in health education, in nutrition, in the laboratory, dentists, and others.

The degree to which the public health ranks are being depleted is shown by our Association's placement service. This service, incidentally, charges neither employer nor employee. It attempts to help fill the thousands of vacant positions in public health in this country—doctors and dentists, engineers, laboratory workers, health educators, and others upon whose work the public health depends. The number of applicants for these positions is roughly one for each five openings (on January 31 last, 157 candidates for jobs and 738 vacancies). In the case of physicians, the ratio is one applicant for nine positions. On February 14, there were on file in our office, 386 requests for public health physicians, the state and local departments concerned offering a minimum salary averaging \$4,878. These positions called, on the average, for 11 years of training after leaving high school. In our files on the same date were but 48 physicians applying for such posts and asking, on the average, for a minimum salary of \$5,652.

It should be remembered that "economy" does not necessarily mean keeping a dollar in your individual or collective pocket. The word, in its derivative sense means "wise management of the household." It is wise economy and sound management to spend dollars to save lives. The death of a child living on a backstreet, or on the edge of a swamp or in a mountain cabin, the convulsions of an expectant mother, an epidemic of one sort or another, are the kinds of things that happen inevitably when public health service is inadequate or when it is performed by persons not trained for work which unremittingly tests knowledge, experience, and judgment.

The only solution of this problem is to reclassify our public health positions so that they will provide sufficient salaries to attract and hold competent professional workers. Just what these salaries should be in an individual city or state is a matter for local decision. All in all, it would seem probable that most states and cities will need an average of at least 20 per cent increase in salaries if they are to hold their present workers and attract new ones who are competent. In many communities the rate of increase should be much greater.

In the case of state health departments, the time to act is now—before the present sitting legislatures adjourn. Parsimony rather than true economy may cost us heavily in lives during the year, or the biennium to come.

Here are a few of the storm warnings in the public health field:

One-third of the people of the nation are without the services of a local health department organized on a full-time basis.

One out of every five, or more than 1 000 full-time health departments serving the other two-thirds of the population, are without health officers.

Fewer than half the counties of the United States have organized full-time public health protection.

An average of only 61 cents per capita was spent for local health service in 1942 in the face of an estimated need of at least \$1 per capita.

The physicians and engineers who are currently receiving graduate public health training are fewer than the number needed to fill existing vacancies.

The salaries paid to public health nurses are in many—perhaps most—health departments below the decent subsistence level for a self-respecting professional.

The universal opinion of state health officers is that lack of personnel is the chief obstacle to extending health protection in their states.

Unfavorable salary levels represent the outstanding difficulty in securing public health personnel.

Are our public health defenses crumbling?

Credit Lines

COLORADO'S ATOM BOMB

The exciting story of what happens when an irresistible force meets an immovable object is told humorously, colloquially, but nevertheless tellingly in the February *Survey Graphic*. The irresistible force in this instance is Florence Sabin, M.D., the immovable object the Colorado state public health situation.

In an article entitled "Dr. Sabin's Second Career," Albert Q. Maisel tells how the "little old lady," as they call her in Colorado, came home to retire, was made chairman of the Subcommittee on Health of the state's Postwar Planning Committee on the theory that her age would keep her close to her fireside and her knitting.

Before anyone was aware of it she was needling every politician, dairyman, and industrialist about Colorado's backward health program, its high diphtheria, scarlet fever, and infant mortality rates, lack of modern sewage disposal and many other unfavorable conditions.

And how did she do this? Well, first she got a state survey by Carl Buck, Dr.P.H., Field Director of the American Public Health Association. Then she told the story of its findings everywhere, and she outlasted everyone else in riding through snowdrifts to speak in little towns; she got the help of all sorts of people who were surprised to find they had pledged themselves to her program; she got people to introduce health bills to which they started out by being hostile. The Democratic Governor says the Republican legislature will pass the program of her Subcommittee because "there isn't a man in the legislature who wants to tangle

with her." And all the time she is reported to be so gentle "you think you're dealing with Whistler's Mother," as one man put it. She is said to have "an amazing ability to open hostile minds, to win people over."

The moral of the tale: Get an atom bomb if your state health department structure and performance need overhauling.

RELIGION IN ACTION

An interesting illustration of the concern of religion with current life is the Statement on Legislative Policy by the Friends Committee on National Legislation for 1947. Among other purposes for which legislation is recommended are: generous support for the Public Health Service for adequate medical research, care of the mentally ill, extended health service in schools and for the campaign to eliminate venereal disease; and for ratification of the proposed World Health Organization Constitution and appropriation of the United States' share of its budget. Available from Friends Committee on National Legislation, 2111 Florida Ave., N.W., Washington 8.

AIDS TO HEALTH EDUCATION IN WASHINGTON STATE

The Washington State Department of Health (1412 Smith Tower, Seattle 4) has prepared a *Bibliography of Pamphlets* for distribution to local health agencies. In addition to a page of suggestions as to when and how to use what pamphlets, there is a listing of the pamphlets by subject. All of the material listed is available without charge in reasonable quantities from the state or local health departments. For those

who want quantity distribution, however, they are also listed by original distributor with indication as to cost. Frequent supplements to the bibliography are planned.

ECONOMIC SECURITY FOR NURSES

The nursing profession has been in the lead among the several public health groups in bringing unfavorable salary conditions to public attention. At its biennial meeting in 1946 the American Nurses' Association adopted the Economic Security Program by which the state and local associations are urged to become the exclusive agents of their respective members in the fields of economic security and collective bargaining.

Now the Nursing Information Bureau of the American Nurses' Association (with the National League for Nursing Education and National Organization for Public Health Nursing) has prepared a fact sheet of 21 questions and answers about the program. It is designed for editors and others who may be writing about these problems, is written in clear and simple language, and should contribute much to general understanding that salaries and other conditions of work are related to quality of nursing service.

Available from Nursing Information Bureau, 1790 Broadway, New York 19.

THE RED CROSS DURING SEVEN WAR YEARS

The American Red Cross recently published a report of its service record for the seven years ending June 30, 1946, a period encompassing all of World War II and part of the uneasy peace following. Although done in black and white, its eye appeal is outstanding for the type (multilith process) is clear-cut, the paper is good, and the pictorial charts imaginatively drawn.

Perhaps the most striking feature of this report is the number of volunteers

and the total hours served—a record of citizen concern that might well serve for peacetime as well. Says Basil O'Connor in the foreword, "Here in sharp focus is a picture of our continuing campaign to alleviate the suffering caused by war and disaster and to broaden the scope of community work in safety, health, and general welfare. For the Red Cross the war against human suffering never ends."

Available from American National Red Cross, Washington, D. C.

THE RAT CONTROLLER

The Health Division of the St. Louis city government is out to rid the city of rats. Following the recent passage of a city ordinance it established a Rat Control Section in the Health Division. Its Director is John Sadowski, a chemical engineer with experience in the St. Louis Water Department, the Milk Control Section of the Health Division, and the Housing and Neighborhood Study.

As part of the rat control program the new section is publishing a monthly news sheet, entitled "The Rat Controller." Vol. 1, No. 1, appeared in February, 1947. This tells of the rat control activities carried on by the Unit. It also tells what part the average citizen has in this campaign. The news sheet is good health education material for which its Editor, Robert M. North, Education Service Supervisor, is to be congratulated. Copies available from Room 62, Municipal Courts Building, St. Louis, Mo.

TUBERCULOSIS INDEX

The first volume of what is reported to be the "only publication of its kind in the world" was recently received from England at the moment when her coal crisis was at its most critical stage. It is the quarterly *Tuberculosis Index and Abstracts of Current Literature*. Its object is "to provide a complete list

of current articles on all aspects of tuberculosis as they appear in world scientific, medical, and sociological literature." The first issue, September, 1946, includes material published in April, May, and June. Our congratulations to the Editorial Board of the *Index* for initiating this work. The quarterly is available from Tavistock House, Tavistock Square, London, W.C. I, England, at \$5 per year.

CONNECTICUT MOVES TOWARD HEALTH UNITS

For 30 years Connecticut has had a law permitting groups of towns (you remember that the town has been the important unit of local government in New England since Colonial days) to form sanitary health districts. For a full dozen years it has had a bill under consideration authorizing cities, towns, and boroughs to unite to form health districts large enough to sustain a full-time district department of health. In the successive legislative sessions of 1941, 1943, and 1945, bills that would have provided state aid to such consolidated health districts were defeated. At the beginning of 1947 only half of the state's population—in 13 cities—had the services of a full-time health officer and no rural area had such service.

But the February 17 *Weekly Bulletin* of the State Department of Health indicates that a new day may be ahead. Again the State Health Department has sponsored a bill for state aid to consolidated health districts, known as the Health District Bill—this time, however, with a difference. Now it can point to resolutions of the Connecticut Health Officers' Association, the Connecticut State Medical Society, the Connecticut Tuberculosis Association, the Connecticut Parent-Teacher Association, the Connecticut Public Health Nursing Organization, and the Connecticut League of Women Voters in favor of

full-time health service throughout the state and of the proposed Health District Bill. If the Connecticut legislators haven't already noticed that the three last mentioned of the above organizations are made up of women, they'd better remember now the old line that "Hell hath no fury like a woman scorned."

"POST GRADUATE MEDICINE" MAKES ITS BOW

In January, 1947, *Post Graduate Medicine* was launched as the official monthly journal of the Postgraduate Medical Association of North America. It will contain the papers and diagnostic clinics presented at the annual meeting of the Postgraduate Association which have hitherto been published in a single annual volume. The *Journal* has an informal editorial approach, keeping in mind the reader, the average general practitioner, first as human being, second as scientist. Legible typography and illustrative material point up the text. Business Manager, Paul K. Whipple, 515 Essex Building, Minneapolis. Price \$8.00 per year.

RICHLAND COUNTY'S ANNUAL REPORT

There are a number of notable things about the Mansfield City and Richland County (Ohio) Health Department *Annual Report* for 1946. Emphasizing the shortage of medical health officers is the fact that this county of more than 70,000, although with an organized full-time health department for a number of years, had three health commissioners during the year, two of them serving part-time and no one of them serving as much as six months. The report is signed by a fourth commissioner, Fred O. Tonney, M.D., who took office at the beginning of 1947.

The second notable item is the Commissioner's frank statement that the 50 cents per capita spent by the city

and county (68 cents including federal funds) for health services is only half of what is required "to provide a minimum of acceptable health protection for any community." Among the deficiencies that are pointed out are lack of public health nursing service to expectant mothers, insufficient school health services, lack of dental service to indigent children in rural areas, lack of coordinated effort toward cancer control, and inadequate food and milk inspection.

If the citizens will read and heed the first two pages of Dr. Tonney's report there is no reason why they should not have the complete modern health department for Richland and Mansfield County that he says is possible with the pooling of urban and rural financial resources.

AIDS FOR CITIZEN DISCUSSION

The National Planning Association has recently put out a new type of publication on an experimental basis. It is called "Dare Farmers Risk Abundance?" which is a combined report of the Agricultural Committee and a *Program Discussion Guide* for a group discussion of farm price and production problems. The *Program Guide* is a folder that fits as a cover of the pamphlet. It has a picture of the classroom and says, "This is your seat. Turn over the page and let's get started." The technique might easily be applied to a discussion, say of community health problems. Pamphlet and guide available from National Planning Association, 800 21st St., N.W., Washington 6, D. C. 25 cents.

MULTIPLE SCLEROSIS EDUCATION

The Association for the Advancement of Research on Multiple Sclerosis (see November *Journal*, p. 1357) has recently published *Educational Pamphlet No. 1*, a brief discussion of the prevalence of the disease, its significance

as a social problem, its cause, and treatment. It is written for the lay reader as a part of the association's campaign to get support for work in behalf of the sufferers from this disease. Available from the Association for Advancement of Research on Multiple Sclerosis, Inc., Fifth Avenue and 103rd Street, New York 29, N. Y.

KANSAS TELLS ITS PUBLIC

The *Monthly News Letter* of the Kansas State Board of Health starts the year 1947 with a new department, "What We Do!" Here it is planned to publish a series of articles on the work of the various divisions of the State Board of Health in order to keep the allied professions, other state and local officials, and the general public informed of the objectives and activities of public health agencies. The first article by Leon R. Kramer, D.D.S., outlines the work of the dental division which has three phases: research, education, and care.

FOR MATERNITY CLINICS

The February *Briefs* of the Maternity Center Association (654 Madison Avenue, New York 21) publishes a talk by the English obstetrician, Grantly Dick Read, M.D., outlining his philosophic approach to pain in childbirth, together with comments of two other obstetricians, George W. Kosmak, M.D., and Blackwell Sawyer, M.D. "The interest in this system of education and relaxation beginning in early pregnancy has been so great," say the editors of *Briefs* that they "consider it a mandate to print a digest of his remarks for all to study."

"RHEUMATIC FEVER: CHILDHOOD'S GREATEST ENEMY"

National Heart Week, February 9, was observed by the Public Affairs Committee with the publication of its pamphlet No. 126, *Rheumatic Fever:*

Childhood's Greatest Enemy. Comprehensive and readable, its 32 illustrated pages give the essential facts about rheumatic fever and indicate the co-ordinated community action needed. It also describes the London County Council's Rheumatism Scheme through which one hospital bed for every 550 school children is provided. The New York City ratio is only a fourth or fifth as high.

Available from Public Affairs Committee, 22 East 38th Street, New York 16. 10 cents.

PUBLIC AFFAIRS DEPARTMENT IN
LADIES HOME JOURNAL

In the March issue the *Ladies Home Journal* (Curtis Publishing Co., Philadelphia 5), started a Public Affairs Department under the editorship of Margaret Hickey. In this first issue "It's Time to Volunteer Again" illustrates how, even with war needs no longer present, the volunteer task is still a continuing one and "The Volunteer Worker, 1947 Style" tells the story of Denver's post-war organization of volunteers.

This new department will maintain a consultation service as well as print articles on treatment of common community ills. Miss Hickey is on the St. Louis Social Planning Council and the Veterans' Demobilization and Reemployment Committee. During the war she was chairman of the Women's Advisory Committee of the War Manpower Commission. From 1944 to 1946, she was president of the National Federation of Business and Professional Women's Clubs.

CAN SCIENTIFIC EXHIBITS BE
EVALUATED?

The A.P.H.A. Committee on Scientific Exhibits takes its job rather seriously. Some of you may have wondered what on earth the committee members were doing at the Cleveland meeting wander-

ing around the exhibits and checking off items on a complicated questionnaire.

Now we know the answer. They were asking themselves, "Why have a scientific exhibit? What message is each scientific exhibitor trying to put across? How successful is he? In what way do the exhibits contribute to the annual meeting?"

There seems to be no foolproof measuring rod to tell us what the innocent onlooker gets out of an exhibit. At the time of the New York World's Fair an effort was made to determine the teaching value of health exhibits. Yet, even if Mr. Citizen learns a new fact, does he behave differently the next day? Much research remains to be done in this field.

Without pretending to assess the educational values, the committee did rate the various exhibits subjectively as to which seemed to state its message most clearly, and made effective use of such exhibit techniques as proper kind of lettering, attractive color, inconspicuous but effective lighting, and art work. On this basis the committee members felt that the following were the four best exhibits in Cleveland:

Division of Cancer Control—New York State
Department of Health
National Foundation for Infantile Paralysis
Preventive Medicine Division, U. S. Army
U. S. Public Health Service

The New York State exhibit with the talking mirror rated high because of its original method of getting audience participation, giving a personal answer to specific questions. The National Foundation for Infantile Paralysis exhibit provided for some audience participation and had excellent three-dimensional sections which reported on progress in seven different aspects of the poliomyelitis problem. The U. S. Army presentation capitalized on everyone's interest in how military authorities had handled global health problems and made good use of several tech-

niques. The U. S. Public Health Service display attracted attention to its unusual arrangement, using large, light frames to display excellent photographs and drawings illustrating ten special fields of activity.

One is inclined to question the effectiveness of an exhibit with seven or ten sections, but the committee was forced to admit that at least the audience is made aware of the broad interests of the agency concerned.

Material presented in the scientific exhibit may reach an even wider audience than listens to a formal paper. Often a weary Association member is torn between attendance at several section meetings. When a timely subject is presented in exhibit form, however, it is possible to take it in at one's leisure and to talk over mutual interests with the booth attendants. It augurs well for the Atlantic City meeting that there will be even more space for Scientific Exhibits. The committee has been encouraged to believe members of the Health Education Section will participate in rating the exhibits. If this is done, the exhibitors will have the benefit of a larger body of professional opinion.

ALONG THE WAY TO SCHOOL HEALTH

School Administrator, Physician, and Nurse in the School Health Program—Functions and Education is a report recently published by the Metropolitan

Life Insurance Co. It is sponsored by the National Conference for Coöperation in Health Education, which has 45 member agencies, among them the American Public Health Association.

The report grew out of a series of three discussion conferences dealing respectively with the nurse, the physician, and the administrator. Each conference divided itself into four smaller groups on home and community relationships, school health services, control of environment, and health education, respectively. The final report was then fashioned out of these 12 separate reports by a coördinating committee whose chairman was Clair E. Turner, D.Sc.

The report has two values: its addition to the sum of knowledge as to what school health service should encompass and what training its practitioners should be armed with; it also is valuable in illustrating a technique for discussion and planning, a technique that utilizes the democratic play of mind upon mind. In this connection the procedure of the conferences is fully outlined.

It is expected that future conferences will be held relating to the functions and education of other professions in the school health program—public health administrators, teachers, dentists, nutritionists, and others.

Available from the Metropolitan Life Insurance Co., New York, San Francisco, or Ottawa.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted. All books reviewed in these columns may be purchased through the Book Service.

Hygiene—By F. L. Meredith, B.Sc., M.D. (4th ed.) Philadelphia: Blakiston, 1946. 838 pp. Price, \$4.00.

The philosophy underlying the approach to the problems of health in *Hygiene* finds expression in the modern idea that man is a unit and that the purpose of life is to function, to live fully in carrying out some worthy purpose in life. *Hygiene* is of value only as its teachings are translated into living, and the theme running through this edition is "what health situations exist in the life of individuals and peoples, what health objectives arise from them, and what action is scientifically appropriate on the part of the layman, especially the college student?"

This 4th edition is an extensive book covering wide fields of health and including not only personal hygiene but important aspects of public health. The revision has been complete with inclusion of new findings in medical science and a rearrangement of material. The general organization of subject matter is excellent, although some teachers might prefer a greater unification of the material dealing with the various aspects of personal hygiene. Everyone, either consciously or unconsciously, strives to attain certain recognized health objectives. The author has placed considerable emphasis on the hygiene of everyday life. The methods by which one may find an answer to his personal problems are suggested and discussed.

"Forces for Health," one of the introductory units, makes a special contribution to the book. In it are discussed the agencies developed by man in

his war against disease and ill health. Included also is a chapter on the beginning of medicine which is of much interest and cultural value. This same interest in the historical aspect of the subject finds frequent expression throughout the book. Reproduction and mental health are discussed at length. Because of the current interest in these subjects, the college student will find their discussion not only interesting but very helpful.

Hygiene is excellent in its approach to the problems of health. It contains extensive and valuable material interestingly presented for both teachers and students.

W. R. MORRISON

Psychoanalytic Therapy — By Franz Alexander, M.D., and Thomas Morton French, M.D. New York: Ronald Press Co., 1946. 353 pp. Price, \$5.00.

This book is an important contribution to methods of psychotherapy, their evaluation, and their relation to traditional psychoanalytic procedures which are also subjected to critical study. It is written with a minimum of technical terms and would be useful to any doctor interested in keeping abreast with trends in psychiatry. It illustrates clearly a wide variety of cases treated by different doctors, and the many different practical ways in which the dynamic principles of psychoanalysis can be employed for short therapy. It also recognizes the need for long-term treatment in other cases, although emphasizing the fact that there are disadvantages to any routine procedure.

The methods described are not novel,

but their systematic use in carefully planned therapy, in which the doctor consciously uses his observations of the patient and his knowledge of psychopathology and dynamics, is very different from the more or less haphazard "intuitive" therapy often practised. The goals and methods of treatment in terms of the treatability of the patient are discussed for various types of problems. There is no effort to reconstruct the past history of the patient in its entirety, but attention is "focused upon the patient's problem in adjusting to the present external reality." The patient is helped to find a new solution for his old unsettled conflicts, whether through relationship to the doctor or in his everyday life. A large number of the cases are neurotic breakdowns on formerly well adjusted individuals, although other types are illustrated.

The importance of this study to public health lies in the prevention of chronic or more serious developments in many patients.

FLORENCE POWDERMAKER

The Health of the School Child—
By Gertrude E. Cromwell, R.N. Philadelphia: Saunders, 1946. 256 pp. 46 illus. Price, \$2.50.

This book on school nursing is based on progressive and sound principles. The discussion centers around the needs of the child while he is in school and various ways school personnel, particularly the school nurse, can foster his optimal growth and development. For the most part the author has a well rounded point of view and presents the results of the more important of modern studies in the field. The great need for more scientific and definitive studies is clear, but the author of this volume cannot be held responsible for the fact that there is often little but opinion to guide her. That she has chosen so wisely is the reader's good fortune.

This reader, however, wondered why

so much emphasis was given to the Snellen test for visual acuity and the Massachusetts Vision or other screening tests were not discussed. Similarly there was no mention of the pitch tone audiometer, or newer methods of treatment of scabies and pediculosis. The problem of tuberculosis in school personnel was not discussed. Nor was the American Public Health Association's useful volume on the control of communicable diseases included in the bibliography. But such minor omissions should not retard the wide use of this excellent little book by school nurses, doctors, health officers, health educators, school officials, and others interested in the health of school children. It is probable that the book will prove most valuable to interested lay persons.

LEONA BAUMGARTNER

Nutrition in Public Health—
By Lucy H. Gillett. Philadelphia: Saunders, 1946. 303 pp. Price, \$2.75.

The author of this book displays a comprehensive understanding of family nutrition problems as they are affected by habit, education, economic status, available food, and racial customs. In dealing with these problems, the food for the various members of the family is evaluated. If changes need to be made there are suggestions for the food needed or a substitute. The author always remembers that she is dealing with human beings when changes are needed in food habits.

A daily food guide that is similar to the "basic seven" pattern is used. The nutritive value of various foods is presented in simple but effective tables or charts. Well chosen photographs and illustrations also enhance the text.

In addition to the public health nurse, the book will be useful for any person teaching nutrition to families. Many laymen would also find it a helpful guide for better nutrition.

LOLA T. DUDGEON

Your Health and Safety—By *Jessie Williams Clemensen and William Ralph La Porte*. New York: Harcourt Brace, 1946. 592 pp. Price, \$2.12.

Attractively printed and illustrated, this high school text now is revised along two major lines—(1) all material, including the 75 pages on safety, has been brought up to date and somewhat expanded; and (2) the style of approach is dramatically improved.

Personalized, as the title infers, the text appeals to youth to seek scientific advice and "avoid the consequences of uninformed conduct."

Scientific material covering the fields of physiology, nutrition, disease prevention, public health protection and safety is jet propelled, as it were, to give strong motivation to action in control over body and mind and the development of a normal personality. The student is forewarned that at every period in life health is attained only by intelligent application of scientific findings and alertness to avoid accidents and sickness.

Devices to attract interest include activity charts, habit check lists, charts to help analyze physical, mental, emotional, and social health.

Featured are an excellent index, a 13 page glossary, and an 8 page appendix of source material.

ETHEL M. HENDRICKSEN

Infant and Child in the Culture of Today—By *Arnold Gesell, M.D., and Frances L. Ilg, M.D.* New York: Harper, 1946. 399 pp. Price, \$4.00.

This excellent book presents the overall mental development of the child from birth to school age soundly and conservatively. It deals with the difficulties of the child in his attempts to mature in today's complex culture. Norms of development for different ages are interpreted in terse, useful form. There is a useful chapter on the nursery school and also a long section

on the guidance of growth which includes problems such as bowel and bladder control, and sex education, discussed with practical reference to the child's developed capabilities. The Appendix contains a description of the Yale Guidance Nursery and an expert list of books and music suitable for children.

The book will prove valuable to the pediatrician as well as the intelligent layman. The authors' style is elaborate, occasionally resulting in difficult reading, but the meaning is everywhere clear and its many editions testify to the book's lay popularity.

STUART S. STEVENSON

Sex, Marriage and Family—By *Thurman B. Rice, M.D.* Philadelphia: Lippincott, 1946. 272 pp. Price, \$2.50.

A decent book full of common sense, a natural and sound philosophy, and a gentle tolerance of the manifestations of human biology in the contemporary social setting.

The fifteen chapters deal with three major topics with which the author, for many years a health educator and administrator, has dealt in person professionally and by the printed and spoken word from official platforms with successful influence.

The first six chapters treat of the beginnings and meaning of mating and marriage. The next five with the coming of the baby, something of the economics and social philosophy of marriage, and some of the factors determining the choice of husband and wife. The last four chapters deal with war and post-war problems of the young people who are the present hope of a confused world and are themselves the victims of an unoriented and rather crude emotional outlook upon marriage and the rearing of children.

Among the many attempts to pass on a clean and tender pattern of life from the leaving to the coming generation,

this book by a gentle and hopeful physician stands out, above most of its competitors in a crowded field, for its sanity, its temperance and balance of spirit.

Many of the young and their elders will read it with simple pleasure. The three page index is adequate for its purpose.

The book can be recommended to the lay public for self-education.

HAVEN EMERSON

DDT and the Insect Problem—

By James C. Leary, William I. Fishbein, and Lawrence C. Salter. New York: McGraw-Hill, 1946. 176 pp. Price, \$2.50.

The advent of DDT produced widespread advances and major modifications in the field of insect control, and this book serves as a welcome supplement to modernize volumes previously written on insect control. Framed in the language of the layman, but well grounded in scientific accuracy, it presents clearly and concisely the fundamental facts and observations for the use of DDT and contains a rather extensive bibliography of the more important research in the field. Consideration is given to the utility of DDT for combating insect disease-vectors, household and agricultural pests, with additional brief discussions on the chemistry and history of DDT, and the rôle that it played as a weapon against disease in World War II.

M. D. HOLLIS

School Boards in Action—*Twenty-fourth Yearbook of the American Association of School Administrators.* Washington, D. C.: National Education Association, 1946. 412 pp. Price, \$2.00.

This is a handbook for school board members and sets forth guiding principles, with concrete examples, which will help school board members to solve complex local problems. Data fur-

nished by more than 3,000 city and county school superintendents, board members, and other educational officials were utilized by the commission which prepared this report.

At first glance the book might be considered outside the interests of public health. This reviewer, however, believes that it warrants the thoughtful attention of those health workers who are striving to improve community health standards. "Good planning procedures on the part of a board of education require coöperative effort between the board and other community agencies, such as those concerned with planning improvements in community health, recreation, welfare, and community development." This statement is quoted from "Signposts for Service," summarizing the chapter on "Planning Better Schools for the Future."

Men and women to the number of nearly 400,000 make up the school boards of this country. These boards are legally empowered "to erect buildings, to hire teachers, to select courses of study and textbooks, to decide upon length of school terms, and to fix amounts to be raised by taxes for schools." Health considerations are implicit in all of these responsibilities.

Professional standards in education as in public health are rising, and it is heartening to have this evidence of the high standards expected of school board members. The plan of summarizing each chapter in a series of short paragraphs entitled "Signposts of Service," enables the reader to survey quickly the contents of the book.

LOUISE STRACHAN

Directory of Biological Laboratories. With Buyers' Guide—*Chicago: Burns Compiling and Research Organization, 1946.* 120 pp. Price, \$3.00.

The first section of this directory lists by states the commercial biological

laboratories of the United States. Clinical and public health laboratories are omitted, although certain laboratories operated by the federal government are included. The functions and characteristics of each laboratory are listed, together with the name of the individual acting as purchasing agent.

The second section lists manufacturers and distributors of laboratory apparatus, materials, supplies, instruments, equipment, etc. These are arranged alphabetically by products and include complete mail addresses. This section should be of value to the laboratory director seeking new sources of supply or an unusual item.

E. K. KLINE

Victory Over Pain—By Victor Robinson, M.D. New York: Henry Schuman, 1946. 338 pp. Price, \$3.50.

The theme of this delightfully written history of anesthesia is well summarized by the last paragraph of the author's introduction: "This book, written on the eve of the centennial of merciful surgery, relates the long struggle of science against suffering, unsuccessful for ages and seemingly no nearer the goal—until the unexpected achievement. The revelation of anesthesia is a chapter in the life of science where it merges with the history of humanity: as such it should be part of the general education of the present generation."

Presentation of this fascinating subject is unique, consisting of biographical sketches of men who contributed to our knowledge of anesthesia and connecting chapters that furnish continuity. The sketches are real drama in which the pioneers of anesthetics seem to live once more surrounded by all of the uncertainties, blunders, and human jealousies of their time; yet each sketch is well documented for historical accuracy. Such men as Long, Jackson, Morton, Simpson, and Koller are portrayed as

actors on the stage of scientific progress in the conquest of pain. The author demonstrates the fine art of presenting history that is highly entertaining yet acceptable in fact. The factual value of the book is enhanced by a selected and annotated bibliography and by an author-subject index.

CHARLES E. SHEPARD

Community Centers as Living War Memorials—Compiled by James Dahir. New York: Russell Sage Foundation, 1946. 63 pp. Price, \$.50.

Since many community groups in this country are today confronted with the problem of planning suitable memorials, Mr. Dahir has performed a most valuable service by compiling a bibliography of interesting, informative, and current literature on the various aspects of group activities in general and community centers in particular. He has traced the purpose and the growth of such projects through the years and has described the various types that exist in this country.

Emphasis is placed on the expressed desire of service men for purposeful war memorials in place of the usual statues that were erected immediately after World War I.

Mr. Dahir has selected definitive material which vividly portrays the numerous activities of community centers and which depicts the great need that exists for similar programs on a nation-wide scale. This book is of particular value to those groups and agencies at present concerned with planning war memorials.

CHARLES F. WILINSKY

The Money Value of a Man—By Louis I. Dublin and Alfred J. Lotka. (rev. ed.) New York: Ronald Press, 1946. 214 pp. Price, \$6.00.

This important book was published by Drs. Dublin and Lotka in 1930. It has been adequately revised in the 1946 edition, and has been brought

forward to meet the changing conditions and the modifications in our economic and social concepts.

To the revised edition have been added chapters on The American Family, Income in Relation to Age and Economic Status, Social Insurance in Relation to the Money Value of a Man, and an Appendix B, entitled "Age Schedules of Family Consumption Units and Savings."

The money values are calculated on the basis of the purchasing power of the dollar in 1946, and in accordance with recent social concepts of increased community responsibility.

This book has had, and should continue to have, a profound influence on public health. The authors present the unique point of view that each individual in the community is a community asset. These assets may be safeguarded, protected, and conserved, as are other financial assets of the community, or they may be destroyed, wasted, discarded, or carelessly thrown away. The authors have demonstrated, in dollars and cents, just what a man is worth to his family and to his community. They have demonstrated also that disease of an individual causes a financial loss to the community—a loss which can be measured and computed. They also have demonstrated that preventive medicine and public health yield financial benefits to the community, and have shown that these benefits can be determined in a perfectly simple but concrete way.

This book is recommended to every public health administrator as an essential book of reference.

W. G. SMILLIE

Daniel Coit Gilman: Creator of the American Type of University—By Abraham Flexner. New York: Harcourt, Brace, 1946. 164 pp. Price, \$2.00.

If one man were to be selected as responsible for the modern concept of

graduate university training in the United States, that man undoubtedly would be Daniel Coit Gilman, the first president of The Johns Hopkins University. The passage of some three-quarters of a century since his inauguration to that office has disclosed more firmly than ever the essential validity of the revolutionary changes in higher learning which he instituted and accomplished almost singlehanded in a new university in only twenty-five years.

Dr. Flexner, himself a product of that university, and responsible in no small measure for the general development of graduate education in this country, does a major service to the present generation in summarizing within small compass the seminal ideas and ideals of Gilman. The volume is a history of ideas rather than a formal biography of a man. Other lives of Gilman supply the missing or understressed features of his history.

Every student of the educational process will profit in re-learning the essential elements of graduate training in medicine, in the physical sciences, in the humanities, and in the classics, as they were impressed upon this country by the vision and the persistence of one man! The story is simply, briefly, and cogently told. The author's theme does not once escape us, as epitomized in Gilman's own words: "The real efficiency of a college is admitted to consist, not in buildings, nor in sites, nor in apparatus, but in the number and character of the teachers employed."

ABEL WOLMAN

Notes on Nursing: What It Is and What It Is Not—By Florence Nightingale. London: Harrison, 59, Pall Mall, 1859. Reprinted by J. B. Lippincott Company, Philadelphia, 1946; and by D. Appleton-Century Company, New York, 1946. 79 pp. Price, \$1.25.

That two of our large publishing

firms should issue a reprint of Florence Nightingale's *Notes on Nursing* in the same year, one from the first edition printed in London in 1859, and one from the first edition published in 1860 in New York, permits, we presume, three deductions: that the other printings of the first edition have been exhausted, that students are still reading, by assignment or by choice, these "momentous minutiae," and that there is something so timeless, so practical and precious to nurses that they are eager to possess their own copies of the original *Notes*.

A rereading never fails to leave one

amazed at Miss Nightingale's understanding of the sick, of the family, and of nurses.

The *Notes* really need no foreword even today, but these reprints are doubly valuable because of the addition, in the case of the Lippincott edition, of a foreword by Annie W. Goodrich, in the case of the D. Appleton-Century Company reprint, by Virginia M. Dunbar.

It is pleasant to know that every nurse may now own a facsimile of the original *Notes* and realize anew her debt to the indomitable Florence.

DOROTHY DEMING

BOOKS RECEIVED

Listing in this column acknowledges the receipt of books and our appreciation to the senders. Space and the interests of readers will permit review of some, but not all, of the books listed.

- BIOCHEMISTRY OF CANCER. By Jesse P. Greenstein. New York: Academic Press, 1947. 389 pp. Price, \$7.80.
- CHEMOTHERAPEUTIC AND OTHER STUDIES OF TYPHUS. By M. Van Den Ende, *et al.* London: His Majesty's Stationery Office, 1946. 246 pp. Price, \$3.65.
- ENCYCLOPEDIA OF PSYCHOLOGY. Philip Lawrence Harriman, Editor. New York: Philosophical Library, 1946. 897 pp. Price, \$10.00.
- FLAAS OF WESTERN NORTH AMERICA. By C. Andresen Hubbard. Ames, Iowa: Iowa State College Press, 1947. 533 pp. Price, \$6.00.
- HARVEY CUSHING—THE STORY OF A GREAT MEDICAL PIONEER. By John F. Fulton. Springfield, Ill.: Thomas, 1947. 754 pp. 150 illus. Price, \$5.00.
- HEALTH AND FITNESS. By Florence L. Meredith. Boston: Heath, 1947. 325 pp. Price, \$2.20.
- HENRICI'S MOLDS, YEASTS AND ACTINOMYCETES. (2nd ed.) Revised by C. E. Skinner, C. W. Emmons, and H. M. Tsuchiya. New York: Wiley, 1947. 409 pp. Price, \$5.00.
- MEDICINE IN THE CHANGING ORDER. Report of the New York Academy of Medicine Committee on Medicine and the Changing Order. New York: Commonwealth Fund, 1947. 240 pp. Price, \$2.00.
- PENICILLIN IN SYPHILIS. By Joseph Earle Moore. Springfield, Ill.: Thomas, 1947. 319 pp. Price, \$5.00.
- PHYSICAL MEDICINE IN GENERAL PRACTICE. Edited by Arthur L. Watkins. Philadelphia: Lippincott, 1947. 341 pp. Price, \$5.00.
- PRACTICAL PHYSIOLOGICAL CHEMISTRY. By Philip B. Hawk, Bernard L. Oser, and William H. Summerson. (12th ed.) Philadelphia: Blakiston, 1947. 1323 pp. Price, \$10.00.
- RESEARCH AND REGIONAL WELFARE. Edited by Robert E. Coker, with a foreword by Louis R. Wilson. Chapel Hill, N. C.: University of North Carolina, 1946. 229 pp. Price, \$3.00.
- RECENT GROUNDWATER INVESTIGATIONS IN THE NETHERLANDS. Monographs on the Progress of Research in Holland. By W. F. J. M. Krul and F. A. Liefcrinck. New York: Elsevier, 1946. 78 pp. Price, \$1.50.
- SOCIAL WORK YEAR BOOK—1947. Russell H. Kurtz, Editor. New York: Russell Sage Foundation, 1947. 714 pp. Price, \$3.50.
- SURVEY REPORT OF THE SALARY STANDARDIZATION BOARD. New York: State Department of Civil Service, 1947. 301 pp. Price, \$1.50.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

What WHO Is Doing—You'll have to be at home with words like WHO, FAO, ILO, PICAQ, and UNESCO before you can read this report intelligently but once you learn to remember who WHO is, you'll get along fine.

ANON. Progress Toward a World Health Organization. *Pub. Health Rep.* 62, 7:225 (Feb. 14), 1947.

Case Finding and Follow-Up—Twelve years of TB testing and x-ray-ing in Syracuse high schools convinces the authorities there of the continuing values in spreading information, finding cases usually early enough for hopeful treatment, and stopping the spread of infection.

AYLING, W. E. Twelve Years of Tuberculosis Case Finding among High School Pupils. *J. School Health.* 17, 1:13 (Jan.), 1947.

Virtuosity in Film Reading—Those of us who have only a bowing acquaintance with tuberculosis control are apt to think of chest x-raying as a mechanically fool-proof procedure. This paper concludes that the interpretation of films is far from an exact technic and much in need of improvement.

BIRKING, C. C., *et al.* Tuberculosis Case Finding. *J.A.M.A.* 133, 6:359 (Feb. 8), 1947.

Polio Is a Mild Disease—Among 22 children exposed to polio, 14 had a febrile illness between 7 and 25 days after exposure; 15 comparable non-contacts who lived on the same block had no fever. The illness is believed to have been subclinical polio. This experience suggests that the disease is a mild, widespread, highly communicable condition which only very infrequently leaves a residual paralysis. About 5

per cent may have a transient paralysis.

CASEY, A. E., *et al.* Relative Frequency of "Subclinical" Poliomyelitis. *Am. J. Dis. Child.* 72, 6:661 (Dec.), 1946.

Latest Words on Influenza Vaccine—Informal discussion by a man well equipped for the job. He says, "My hunch is that (another 1918 pandemic) would be a strain similar in its basic characteristic to the strains with which we are familiar." Results of vaccination against it would depend on several factors, which he considers.

FRANCIS, T., JR. A Consideration of Vaccination against Influenza. *Milbank Quart.* 25, 1:5 (Jan.), 1947.

Psychic Tension Aggravates It—What bitter medicine these sentences will be for some of us! "Overweight has a strong effect on shortening the life span and increasing the development of degenerative diseases. There is little evidence that obesity is a glandular or metabolic disturbance. The psychologic factors in obesity are paramount, since the tendency to overeat is a strong drive for oral gratification." There is a lot more, but I'll spare you.

FREED, S. C. Psychic Factors in the Development and Treatment of Obesity. *J.A.M.A.* 133, 6:369 (Feb. 8), 1947.

Community or Individual—Which?—We are short 50,000 beds for the tuberculous. Who should be chosen first for the available beds? If the question were answered here, it would encourage you to put off reading these papers—which you shouldn't do.

ASSOCIATION NEWS

SEVENTY-FIFTH ANNUAL MEETING
AMERICAN PUBLIC HEALTH ASSOCIATION
ATLANTIC CITY, N. J., OCTOBER 6-10, 1947

A.P.H.A. TEAM OF SPEAKERS IN WESTERN STATES MAY AND JUNE, 1947

The Association announces that a team of speakers has been organized to attend a series of state and regional public health meetings beginning early in May and extending until the first week in June. This is a pattern similar to that used during 1943, 1944, and 1945, when it was not possible to hold a meeting of the Western Branch, A.P.H.A. This year, however, the Western Branch will definitely hold a meeting in San Francisco, May 27-29, preceded by two days of additional group meetings. The state meetings have been arranged before and after the dates of the Western Branch meeting in order to take advantage of the presence in the West of visitors from other sections and to bring good speakers to those who can attend state meetings but for whom attendance at the Western Branch meeting is not possible. It is expected that a total attendance of several thousand persons will result from the meetings organized by state public health associations and planned by them in the form that will best suit the needs in each state. In so far as team members are desired by the local groups, they will be used for the state programs.

The following schedule of meetings is

in semi-final form and indicates the expectation at the time the *Journal* went to press:

- May 9-10 Missouri Public Health Association, Jefferson City
- May 10-11 North Dakota Public Health Association, Fargo (part of team)
- May 12-13 Minnesota Public Health Conference, Minneapolis
- May 14 Nebraska public health workers, Omaha
- May 16-17 Colorado Public Health Association, Colorado Springs
- May 19-20 New Mexico Public Health Association, Albuquerque
- May 22-23 Arizona Public Health Association, Tucson
- May 27-29 Western Branch, A.P.H.A., San Francisco
- June 2-3 Idaho Public Health Association, Boise
- June 4-5 Utah Public Health Association, Salt Lake City

The team this year will be made up of about ten persons, including Dr. Mary Crosse of Birmingham, England, especially interested in maternal and child health. She is prepared to explain the British system for the care of premature babies, the use of nurse midwives and the administration of nurseries for children. Also included will be Walter J. Pelton, D.D.S., consultant public health dentist on the

staff of the U. S. Public Health Service; two public health nurse team members, each covering part of the circuit, Miss Eleanor Palmquist and Miss Dorothy Rusby, both Assistant Directors, National Organization for Public Health Nursing; Carl E. Buck, Dr.P.H., Field Director, A.P.H.A., will be present at several of the meetings, together with two public health engineers from the A.P.H.A. staff, Francis B. Elder, Engineering Associate and William T. Ingram, Engineering Field Associate. Also Allan Twichell, Technical Secretary, A.P.H.A. Committee on the Hygiene of Housing; Charles B. Frasher, technical consultant in personnel adminis-

tration, A.P.H.A. Merit System Unit; and Reginald M. Atwater, M.D., Executive Secretary, A.P.H.A.

The team members will be prepared again to offer a Roundup Session, in which those in attendance will be encouraged to ask questions which will be debated in public between members of the team, assisted by state representatives, as an illustration of a type of program that has proved provocative in similar meetings.

Persons desiring to attend these meetings should confirm the dates and places with local representatives because of the possibility of a change in final programs.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Charles J. Barone, M.D., 24 Gerald Ave., Highland Park 3, Mich., City Health Officer
 Chester C. Burski, M.D., Rutledge Char. Bldg., Chippewa Falls, Wis., District Health Officer
 Robert M. Lane, M.D., D.P.H., Box 436, Prince Rupert, B.C., Canada, Director, Prince Rupert Health Unit
 Arnold Mills, M.D., 73 Hazelton St., Mattapan 26, Mass., Medical Inspector, Boston Health Dept.
 Colonel Thomas Neilson Page, M.C., Office of the Surgeon, Panama Canal Dept., Quarry Heights, Canal Zone, Asst. Dept. Surgeon, U. S. Army
 Duurt Klass Rykels, M.D., 1733 W. Caroline St., Baltimore 13, Md., Asst. Director, Netherlands Public Health Service
 Thomas C. Sims, M.D., Fayette County Health Dept., Fayetteville, W. Va., Health Officer
 Robert G. Struthers, M.D., D.P.H., 48 St. Andrews Gardens, Toronto, Ont., Canada, Acting Director, Public Health Administration, Ontario Dept. of Health
 James A. Taylor, M.D., D.P.H., Box 377, Nanaimo, B. C., Canada, Director, Central Vancouver Island Health Unit
 Salvatore R. Traina, M.D., 527 Bennington St., East, Boston, Mass., District Health Officer

Triantafylos G. Triantafyllou, M.D., 22 Eptanissou, Athens, Greece, Director, Health Center of Athens
 Norris W. Vaux, M.D., State Dept. of Health, Harrisburg, Pa., State Secy. of Health

Laboratory Section

Martha A. Behan, Antitoxin Laboratory, Otisville, N. Y., Bacteriologist, N. Y. City Dept. of Health
 Albert L. Belcher, 637 N. 37th St., East St. Louis, Ill., Laboratory Technician, East Side Health District
 Herbert R. Brown, M.D., 236 Main St., Dansville, N. Y., Director, Livingston County Laboratory
 Elizabeth C. Chappell, 122 South Stanford, Albuquerque, N. M., Senior Bacteriologist-Serologist, New Mexico State Public Health Laboratory
 George J. Clark, Ph.G., 1027 Second Ave., Columbus, Ga., Senior Medical Technician in Bacteriology, U. S. Public Health Service
 Margaret K. Fiscali, 301 North Santa Rosa Ave., Modesto, Calif., Technician, Clinical Laboratory
 Josephine A. Foote, 125 W. Washington St., Wausau, Wis., Supervisor, State Cooperative Laboratory
 Jean W. Glassen, RFD 4, Box 329B, Lansing, Mich., Public Health Laboratory Scientist

III, Biological Products Division, State Dept. of Health
 John W. Hawkins, Carbondale, Ill., Bacteriologist I, State Dept. of Public Health
 Joseph G. Hoffman, Ph.D., 663 North Oak St., Buffalo, N. Y., Director of Cancer Research, Roswell Park Memorial Institute
 Major L. Roland Kuhn, Sn.C., 6th Army Laboratory, Presidio of Monterey, Calif., Chief, Bacteriology Section
 Ernest C. McCulloch, Ph.D., D.V.M., State College of Washington, Pullman, Wash., Professor of Bacteriology
 Gentry Moffitt, M.A., 2107 Dixie Place, Nashville, Tenn., Bacteriologist, State Dept. of Public Health
 Robert E. Morgan, Florida State Hospital, Chattahoochee, Fla., Chief Medical Technologist
 Theodore M. Pfeffer, 805 S. 15th St., Newark, N. J., Sterile Ampoule Chemist, Schering Corp
 Theodore E. Roy, M.D., C.M., Dept. of Pathology, Hospital for Sick Children, Toronto, Ont., Canada, Bacteriologist
 James G. Shaffer, D.Sc., Vanderbilt University, Nashville, Tenn., Instructor, Dept. of Public Health and Preventive Medicine
 Orval R. Stokke, Box 1020, Bismarck, N. D., Bacteriologist, State Board of Health
 Robert B. Stratton, 516 Greer Bldg., New Castle, Pa., Laboratory Director, Stratton-Page Laboratory
 Charlotte C. VanWinkle, M.D., D.P.H., 620 S. 3rd St., Louisville 2, Ky., Director, Kahn Laboratory, State Board of Health
 Franklin H. White, 1008 Main, Alton, Ill., Bacteriologist, State Dept. of Public Health

Vital Statistics Section

James S. Fuller, 631 Jay St., Sacramento, Calif., Statistician, State Dept. of Public Health
 Ricardo Granillo R., M.D., Sindicalismo 54, Mexico, D. F., Mex., Jefe del Departamento de Estadística, Secretaria de Salubridad y Asistencia
 Anna P. Halkovich, M.B.A., National Office of Vital Statistics, Washington 25, D. C., Statistician
 Irene M. Markowitz, 1031 Ansel Rd., Cleveland, Ohio, Tuberculosis Statistician, Cuyahoga County Tuberculosis Clinic
 Elwood C. Murselman, M.S., State Division of Health, Jefferson City, Mo., Director of Vital Statistics
 Earl R. Thran, 415 E. William St., Ann Arbor, Mich., Student, School of Public Health, University of Michigan

Margaret Zwolak, 1442 Somerset Place, N.W., Apt. 101, Washington 11, D. C., Asst. Research Worker, District of Columbia Tuberculosis Assn.

Engineering Section

John S. Alden, M.S., 512 Burkhardt Ave., Dayton, Ohio, Supervisor, Bureau of Food Inspection and Sanitation, City Division of Health
 Seymour Barfield, 2308 Linden Ave., Long Beach 6, Calif., Junior Sanitation Inspector, Los Angeles City Health Dept.

Bacteriologist, B.S. Experience: State Health Dept. 5 years, recent laboratory officer and instructor in bacteriology, Sanitary Corps, A.U.S. 2½ years. Write Box L-520, Employment Service, A.P.H.A.

Veterinarian chiefly interested in food control (D.V.M. 1940, M.P.H. expected June 1947); seeks position in field of food and drug administration or in food industry (laboratory or advisory). Experience: 2 years' animal disease control work (U. S. Dept. of Agriculture), 1 year meat inspection (Government), 4 years' food control and sanitation (U. S. Army

Veterinary Corps). Write Box V-300, Employment Service, A.P.H.A.

Health Educator, Negro, with Bachelor's and master's degrees in Public Health. Now professor of Health Education in Class A college. Desires position with state or local health organization or other agency in the East or Middle West. Write Box H-528, Employment Service, A.P.H.A.

Engineer, 31 years old, B.S. (C.E.), M.S. (Sanitary Engineering), nine years' experience in public health engineering with state health department, research and teaching in school of public health and school of engineering, desires position on the teaching staff of school of public health or school of engineering, or as public health engineer in state or local health department. Write Box E-505, Employment Service, A.P.H.A.

Negro dental student will graduate in June, holds both B.S. and M.S.P.H. degrees. Seven years of educational and administrative experience. Veteran of World War II. Desires a full-time job with either a State, County, or City Health Department in Dental Education or as a School Dentist. Thirty-four years old. Write Box D-20, Employment Service, A.P.H.A.

Health Educator, trained and experienced in the use of the various media—radio, speakers' bureau, publications, publicity, exhibits. Record of successful

work in community organization, and in planning and directing mass x-ray programs. Write Box H-530, Employment Service, A.P.H.A.

Nutritionist with some hospital dietetic experience and experience in food research and university lecturing for 3 years, desires position as nutritionist in public health department, social agency or health unit in the U. S. Canadian citizen. Write Box N-415, Employment Service, A.P.H.A.

Physician, former Health Unit Director, considerable administrative experience, industrial experience during the war. Seeks part-time position in health work on administrative or clinical basis or as preemployment, school or insurance examiner. New Orleans area. Write Box A-518, Employment Service, A.P.H.A.

Nutritionist, M.S. (nutrition). Experience: State health Department 6½ years, federal agency 1½ years, hospital dietitian 5 years. Write Box N-400, Employment Service, A.P.H.A.

Ph.D., male. Twelve years' experience in teaching and independent research in parasitology, immunology, and bacteriology at university medical schools and research laboratories, desires responsible position in teaching or research institution, governmental agency or industry. Write Box M-473, Employment Service, A.P.H.A.

U. S. Public Health Service Announces Examinations for Nurses

Examinations for the appointment of registered nurses to the U. S. Public Health Service will be given during March and April, 1947, in cities throughout the nation, according to an announcement made by Miss Lucile Petry, Chief of the Division of Nursing.

"The Public Health Service offers opportunities for recent graduates as well as experienced nurses," Miss Petry said.

"For the new registered nurse who can qualify here is an opportunity to acquire good initial experience. The Public Health Service offers the experienced nurse a permanent career with the advantages of professionally stimulating work, job security, regular salary increases, and opportunities for advanced study and promotion on the basis of training and ability."

Nurses interested in obtaining further details concerning appointment to the U. S. Public Health Service should write

to Miss Lucile Petry, Chief, Division of Nursing, U. S. Public Health Service, Washington 25, D. C. Specific dates for examinations will be announced shortly.

Fellowships for Physicians and Engineers

The Surgeon General announces that applications for Fellowships in post-graduate public health training for physicians and engineers, for the school year beginning in the fall of 1947, will be received prior to May 1, 1947. The Fellowships are made possible through a grant given by the National Foundation for Infantile Paralysis.

The Fellowships include nine months of training in an accredited school of public health or an acceptable school of sanitary engineering followed by three months of field training.

Requirements: Under 45 years of age, United States citizenship. Physicians must have completed at least one year's internship. Engineers must have a bachelor's or higher degree in sanitary, civil, or chemical engineering, or another

engineering degree with experience in public health or sanitary engineering.

The Fellowships are intended for newcomers to the public health field and are not open to employees of state or local health departments for whom federal grant-in-aid funds are already available to the states. The purpose of the Fellowships is to aid in the recruitment of medical and engineering personnel to help fill hundreds of vacancies existing in state and local health departments throughout the country.

The Fellowships are administered by the Surgeon General's Committee on Training of Public Health Personnel. Applicants may secure further details by writing to The Surgeon General, U. S. Public Health Service, 19th and Constitution Ave., N.W., Washington 25, D. C.

Public Health Career Opportunities in New York State

Examinations open to residents and non-residents of New York State will be held in May to fill over 20 positions of Assistant District Health Officer and Senior Public Health Physician (Tuberculosis Control): beginning salary \$4,620 with annual increments to \$5,720. An unwritten examination is also scheduled for Assistant Director of Cancer Control with a salary range of \$6,000 to \$7,375.

Because of rapidly expanding programs,

opportunities for promotion to positions with salaries ranging from \$6,000 to \$7,375 will be unusually good after one year's service as Assistant District Health Officer or Senior Public Health Physician (Tuberculosis Control). After further experience members of the staff are eligible for positions paying from \$7,750 to \$9,250 and also for county and city positions paying, in some cases, higher salaries. State service carries with it one month's vacation annually, liberal sick leave, and participation in the state retirement plan.

Qualifications for all positions include citizenship; graduation from a medical school approved by the American Medical Association; license or eligibility for license to practise medicine in New York State; one year's satisfactory internship or equivalent; successful completion of a postgraduate course in public health of one academic year in residence, approved by the New York State Public Health Council; and at least 6 months' satisfactory, full-time experience in a responsible public health position. Experience may be substituted for the postgraduate course in public health. Additional specialized experience is required for the positions of Assistant Director of Cancer Control and Senior Public Health Physician (Tuberculosis Control).

For details write to State Department of Health, Albany 1, New York.

Opportunities Available

WANTED—(a) Director, student health department; full appointment; coeducational institution, approximately 4,000 students; East. (b) Physician with extensive experience in medical society work to serve as executive officer of state medical society; preferably someone around fifty or under. (c) Student health position, liberal arts college; Middle West; apartment or home available. (d) Director of health, public school system; enrollment of 20,000; 800 employees; staff of 12 nurses, two dentists, several oral hygienists; preference for physician who has specialized in pediatrics or public health. (e) Director of student health; duties consist of coordinating medical, health, and physical education services; women's college of approximately 1,200 students; South. (f) Well trained and experienced public health officer to join staff of city health department; Pacific Coast; \$7,200. (g) Medical officer; master's degree in public health and some experience, preferably with rural health program; key position requiring administrative ability; \$7,000; Latin America. PH4-1 Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago 11.

WANTED—(a) Health educator qualified to serve as consultant to health educators on staff of state department of health; Ph.D. whose training has included year of graduate training in field of public health with major emphasis on education required; \$3,600-\$4,800. (b) Sanitary engineer to join division of engineering and sanitation of county department of health; headquarters in large metropolis; Middle West; \$3,000-\$3,500. (c) Health educator to become associated with Chicago agency; master's degree in public health education desirable; \$3,500. (d) Sani-

tary engineer; duties consist of serving in advisory capacity in general overall sanitary and anti-malarial work of large, industrial company; preferably someone free to travel. (e) Health educator; state department of health; general community health education program; preferably someone who has majored in physical education; Master's degree in public health with major in public health education; South. PH4-2 Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago 11.

WANTED—(a) Several public health staff nurses; state organization of 100,000; opportunity for obtaining additional training; \$175-\$215. (b) Assistant professor of public health nursing; duties include service as educational director of city public health service and supervising students for field experience in public health nursing; degree required, Master's preferred; salary dependent upon qualifications; West. (c) Senior public health nurses; duties consist of performing professional nursing services involving generalized public health nursing; work primarily concerned with improvement and maintenance of community health within prescribed areas; \$210-\$250; Pacific Coast. (d) Director, municipal public health nursing association; degree required; must be qualified to develop program; minimum three years' experience; salary dependent upon qualifications. (e) Maternity consultant; state department of health; degree, graduate training in obstetrics and supervisory experience required; Middle West. (f) Public health nurses with fluent knowledge of Spanish to undertake public health work in Argentina for period of 12-18 months. PH4-3 Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago 11.

Opportunities Wanted

Public health physician is available for administrative appointment; Ph.B. degree and degree of doctor of medicine, eastern university; M.S. degree in Public Health Medicine; seven years' public health work which has been largely administrative; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Bacteriologist; Ph.D., several years' experience as hospital bacteriologist; four years, instructor in bacteriology, university medical school; five years, chief bacteriologist in charge of microbiology laboratories, industrial company; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Public health nursing administrator; A.B. and M.S. degrees; professionally trained in university schools; eight years' interesting experience as public health supervisor; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Health educator; B.S., M.S. and Ph.D. degrees; several years, instructor in biology, bacteriology and health; state university; three years, public health educator, city and county health department; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Nutritionist; B.S. in home economics, M.S. in nutrition; year's fellowship in nutrition during which time she completed vitamin assay of foods; several years on faculty of department of nutrition of university school of home economics; is particularly interested in abstracting nutrition studies or collaborating research findings and nutrition advertising; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Sanitary engineer is available for public health appointment; C.E., Eastern university; two years' municipal engineering including supervision of field personnel; six years, sanitary engineer with state department of health where he has obtained broad experience in all phases of environmental sanitation; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Statistician; M.A. degree (Sociological research) graduate training university school of public health (biology, bacteriology and physiology); several years' experience as statistician with state department of health; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

NEWS FROM THE FIELD

ALLOCATING STATE FUNDS TO LOCAL HEALTH DEPARTMENTS

State health officers have recently received from the Association's Committee on Administrative Practice a summary of formulae for allocating state funds to local health departments. Requested by the vote of the September Conference on Local Health Units, such formulae were submitted by eight states—Florida, Georgia, Illinois, Louisiana, New York, North Carolina, Tennessee, and Washington.

At least four of the states reporting—Georgia, Illinois, New York, and Tennessee—make as a condition of receiving state funds the employment of a full-time medical officer of health. Georgia's allocation formula recommends that counties of less than 50,000 population organize themselves into multicounty health districts. Illinois' formula prescribes an annual public health plan as a prerequisite to allocation of funds.

Nearly all of the eight plans submitted have provision for a graduated allocation to local departments depending on population, size of budget, or per capita wealth.

Florida's plan allocates \$1 per capita for the first 10,000 of population, decreasing the amount gradually to 15 cents for the fifth and subsequent 10,000's. This results in a 59 cent per capita allocation for a population of 50,000, 37 cents for 100,000.

Georgia's state participation ranges from 35 per cent of the budget in population units of over 100,000 to 75 per cent in those of 5,000 or less.

Illinois uses the graduated principle to the extent of adding to the standard 20 per cent of total local costs an additional amount for poorer counties based on individual need.

Louisiana allocates from two-thirds to one-sixth of the total local budget, the smallest percentage applying to budgets of \$130,000 or more. For budgets of \$61,000 the maximum state percentage is 32.

New York gives only to organized county health departments 75 per cent of the first

\$100,000 expended, 50 per cent of the amount beyond \$100,000. To cities that are not part of county health departments and to unorganized counties for special services it allocates 50 per cent of total local costs.

North Carolina has a formula based on population weighted by an index of financial need for general health services and an additional weighting for special services by an index of need.

The Washington formula provides \$3 of state money for every \$1 of local money for counties with assessed valuation of from \$300 to \$400 per capita, graduated downward to a ratio of one state to three local in counties with assessed valuation of \$1,000 or more per capita.

As other states furnish their formulae to the Committee on Administrative Practice, they will be summarized and made available to state health administrators.

INDIANA TACKLES RURAL DOCTOR SHORTAGE

The Indiana State Medical Association has undertaken a program whereby it hopes to meet the shortage of physicians in the rural areas of the state. Through its Medical Association Council it is offering six or more scholarships each year for young men and women who wish to study medicine and practise in Indiana. Students accepting the scholarships must agree to be available for private practice in those counties of the state "in which in the opinion of the committee, medical service is most urgently needed." Applications should be made to Alfred Ellison, M.D., Chairman, Medical Association Council, South Bend, Ind.

MORE LOCAL HEALTH SERVICE IN MICHIGAN

In the February issue of *Michigan Public Health*, the State Health Commissioner, William DeKleine, M.D., congratulates several communities of

the state for setting up or strengthening their local health departments. Among those mentioned are Macomb County, population about 110,000, which has established a health department. Delta and Menominee Counties, with a combined population of about 60,000, have organized a bi-county health department whereas previously each had had a separate health department. Chippewa County has joined the previously organized bi-county unit of Luce and Mackinac, thus making a population unit of about 45,000 persons. In congratulating these consolidating counties Dr. DeKleine said, "Your willingness to work together in maintaining consolidated health departments is worthy of high praise. I too firmly believe that 'the strength of the wolf is in the pack.'"

EXPANDED TEACHING PROGRAM IN INDUSTRIAL HYGIENE AT COLUMBIA UNIVERSITY

In order to meet the growing demand for trained personnel, the Columbia University School of Public Health announces courses of study for physicians, nurses, engineers, and chemists chiefly interested in the field of industrial hygiene or occupational medicine. For the academic year starting in September, 1947, properly qualified students will be accepted as candidates for the degree of Master of Public Health or Master of Science in Industrial Hygiene. The curricula will include lectures, seminars, demonstrations, laboratory exercises, and field work.

Students working toward the Master of Public Health degree will be required to take, in addition to their industrial hygiene work, courses in other public health subjects such as biostatistics, epidemiology, administration, sanitary science, and health education. Those enrolled for the Master of Science degree will be permitted to con-

centrate to a greater extent on industrial hygiene subjects.

Further information may be obtained from the Director, Columbia University School of Public Health, 600 West 168th Street, New York 32, New York.

POLIOMYELITIS STAFF TRAINING CONFERENCES

The American Red Cross has been conducting a series of five 2 day area staff training conferences on the subject of poliomyelitis. The purpose was to prepare staff nurses to judge nursing needs in polio outbreaks, to bring them up-to-date on procedures and available facilities, and to provide an opportunity for discussion of problems encountered in nurse recruitment and assignment. Representatives of the National Foundation for Infantile Paralysis and the Children's Bureau, and public health officials and physicians who were active in recent poliomyelitis outbreaks were present at each meeting.

The conference series followed the country's worst polio outbreaks in 30 years, for which the Red Cross recruited 2,360 nurses. The first conference was held in St. Louis, January 23-24, the most recent one in New York City, April 2-3.

TEXAS PUBLIC HEALTH ASSOCIATION

The 22nd Annual Meeting of the Texas Public Health Association was held in Dallas February 24-26 under the Presidency of L. P. Walter, M.D., M.P.H., of the Texas State Department of Health. More than 400 persons were in attendance. Among the out-of-state speakers were Henry F. Vaughan, Dr.P.H., Ann Arbor, Mich.; Wilson T. Sowder, M.D., M.P.H., State Health Officer, Jacksonville, Fla.; Edwin F. Dailey, M.D., U. S. Children's Bureau, Washington, D. C.; Carl E. Buck, Dr. P.H., Field Director, American Public Health Association; William T. Ingram, M.P.H., Engineering Field Associate,

A.P.H.A.; and Reginald M. Atwater, M.D., Executive Secretary, A.P.H.A.

The following officers were elected for the coming year:

President—Sidney W. Bohls, M.D., Austin
President-Elect—Austin E. Hill, M.D., Houston
First Vice-President—Faye Pannell, R.N., Dallas

Second Vice-President—Thomas Bartlett
Executive Secretary—Earle W. Sudderth, Dallas

MENTAL HYGIENE DIVISION IN ARKANSAS

The 1947 Arkansas Legislative Assembly passed a law setting up a Division of Mental Hygiene in the State Board of Health. The professional personnel provided for at the outset includes a psychiatrist, a psychologist, and two psychiatric nurse social workers.

PAY INCREASE FOR NURSES

The Visiting Nurse Service of New York has recently reclassified all salaries on a higher scale and adopted a retirement pension system. The new classifications and their salaries are: practical nurses, \$1,700 to \$1,942 a year; professional (registered) nurses, \$2,280 to \$2,400 a year; public health nurses, \$2,520 to \$3,180 a year; supervisors, \$3,200 to \$4,200 a year.

COLLEGE HEALTH CONFERENCE IN MAY

Thirty-five leading organizations in health and education will sponsor the Third National Conference on Health in Colleges to be held in New York City, May 7-10, 1947. National sponsoring organizations include the Association of American Colleges, the American Association of Teachers Colleges, the American Student Health Association, the American Association for Health, Physical Education and Recreation, and the National Health Council. The proceedings of the Third National Conference on Health in Colleges will

be published in book form. For further information, address the Secretary, 1790 Broadway, New York 19, N. Y.

ILLINOIS DECLARES POLICY ON FOODHANDLER EXAMINATIONS

The Illinois State Health Department recently issued to its Division chiefs and district, county, and municipal health officers, a new policy statement on control measures to prevent spread of disease by foodhandlers and public or private employees.

The policy states that "it is believed that routine physical examinations as generally made have little value in control of diseases and that laboratory examination of specimens submitted in connection with these examinations has little value of a permanent nature."

In place of routine medical and laboratory examinations of all employees four measures are recommended as follows:

1. The improvement and proper use of sanitary facilities—This can best be accomplished by means of a strong sanitation program, with adequate inspection backed by a sound sanitation ordinance. Effective use of the U.S.P.H.S. standard ordinances will improve and control conditions in the food industry.

2. The provision or training in personal hygiene—This can be promoted on a general scale in the health education program by demonstration pamphlets, news releases, radio programs, and sponsored group meetings. Special group meetings with personnel of various branches of food industry, institutions, schools, etc., and special public meetings for miscellaneous groups can be arranged. Management should be impressed with the need for including health education in training programs.

3. The removal from work and treatment of persons who are obviously ill—Management and employees must be made conscious of the importance of this. Only by rigid on-the-spot action can respiratory infections, wounds, etc., be controlled. Personnel policies that encourage full cooperation will accrue to the benefit of personnel, management, and the health of the public.

4. The careful study of epidemiological factors with follow-up of convalescents and contacts—This will concentrate effort at the source of danger and eliminate the necessity of examining all persons as possible carriers.

In connection with this new statement of policy no requirement is established for initial or routine health examinations nor is mention made of specific disease. However, the following wording is suggested for all new or revised rules, regulations, or minimum requirements concerned with medical examination and health of personnel:

1. Every person employed in a maternity hospital, nursing home, milk-pasteurization plant, retail raw dairy, food establishment, etc., shall furnish such information, permit such physical examination, and submit such laboratory specimens as the department may require for the purpose of determining freedom from infection.

2. Any person with an acute respiratory infection or other acute contagious or infectious disease, or a presumably infected wound, sore or lesion shall not be permitted to work in such an establishment or to handle food or food utensils until he has a written statement from the local, county, or state health authority that he is not a disease carrier.

If the manager or superintendent suspects that any employee has contracted any disease in communicable form or has become a carrier of such disease, he shall prohibit further work by such employee and shall notify the nearest health authority immediately.

IN-SERVICE TRAINING COURSE FOR WATER WORKS PERSONNEL

The University of Michigan School of Public Health has announced the second in-service training course in selected technical problems for water works personnel to be held at the School of Public Health, Ann Arbor, Mich., on May 5 and 6, 1947.

The course is designed especially for water chemists of municipal and industrial water treatment plants, but others who are interested will be welcomed.

Application for enrollment should be sent to the School of Public Health

promptly. The closing date for enrollment is April 30, 1947.

NATIONAL SOCIETY FOR THE PREVENTION OF BLINDNESS

The National Society for the Prevention of Blindness offers a prize of \$500 for the most valuable original paper adding to existing knowledge concerning the diagnosis of early glaucoma or the medical treatment of noncongestive glaucoma. Papers may be submitted by any practising ophthalmologist of the Western Hemisphere and may be written in English, French, German, Italian, Spanish, or Portuguese. Criteria for the paper may be secured from the National Society for the Prevention of Blindness, 1790 Broadway, New York 19. Closing date for receipt of papers is December, 1947.

Papers for the prize offered in 1944 did not conform to the criteria set up by the ophthalmological committee. Hence the prize is offered again.

C. G. GILLESPIE RETIRES

C. G. Gillespie has retired from the position of Chief, Bureau of Sanitary Engineering, California Department of Public Health, after 28 years in state service.

He was appointed Chief in 1915, at the time of the organization of the Bureau, and is largely responsible for the development in California of a public health program in sanitary engineering. This is a long range program based on education to affect gradually improved standards and is marked by a 1946 ruling of the State Board of Health that no new permits will be issued for the disposal of raw sewage and industrial wastes into California streams, bays and ocean waters and that outstanding permits for this practice are being revoked as of January 1, 1947.

Mr. Gillespie was recently appointed Special Consultant to the Sanitation

Study Section of the National Institute of Health, which makes recommendations to the National Advisory Health Council on grants for research in the field of environmental sanitation.

DEPARTMENT OF TROPICAL MEDICINE
AND PUBLIC HEALTH FOR
TULANE UNIVERSITY

Plans have been announced for a Department of Tropical Medicine and Public Health at the Tulane University School of Medicine, New Orleans. The department will consist of three units: clinical tropical medicine, parasitology, and public health. Plans are for a course that will lead to a combined degree in tropical medicine and public health, the only other example of which, according to the announcement, is the London School of Hygiene and Tropical Medicine.

The new department will be headed by William A. Sodeman, M.D., who has been head of the Department of Preventive Medicine in Tulane since 1941. He is now carrying on special clinical studies in the Puerto Rico School of Tropical Medicine and will also study tropical diseases and their control in Venezuela and Panama before he takes up his duties as director of the new department, which should be in operation for the academic year 1947-1948.

FIRST POST-WAR NEW ENGLAND
HEALTH INSTITUTE

The New England Health Institute which was discontinued during the war years will be revived during the coming summer on June 16, 17, and 18 at the University of New Hampshire, Durham. The complete program, now being arranged, will be announced at a later date. Facilities of the University will be at the disposal of those attending at an approximate rate of \$2.50 to \$3.50 per day for room and meals. Further information can be secured from H. Shirley Dwyer, D.D.S., Public Relations

Chairman, New England Health Institute, New Hampshire State Department of Health, Concord.

PUERTO RICO PUBLIC HEALTH
ASSOCIATION

The sixth Annual Meeting of the Puerto Rico Public Health Association was held at the School of Tropical Medicine, San Juan, in February. Meetings were presided over by Angel M. Marchand, M.D., M.P.H., President. Participants included Governor Pinero of Puerto Rico, Dr. Juan Antonio Pons, Commissioner of Health of Puerto Rico, James S. Simmons, M.D., Dr.P.H., Dean of the Harvard School of Public Health, John M. Hepler, C.E., Director, Bureau of Engineering, State Department of Health, Lansing, Michigan, Dr. Alfred John Aselmeyer of the U. S. Public Health Service, and others.

The officers for the coming year include Guillermo Arbona, M.D., M.P.H., President, Rafael A. Timothee, M.D., President-Elect, and Nelson Biaggi, Secretary.

PUBLIC HEALTH NURSING WEEK

The second annual Public Health Nursing Week will be April 20-26. The observance of this week is being sponsored by the National Organization for Public Health Nursing with the co-operation of the U. S. Public Health Service and other groups. This is also the occasion of the observance of the 70th anniversary of public health nursing in the United States and the 35th anniversary of the N.O.P.H.N.

The aims of Public Health Nursing Week are:

- a. To stimulate the development of organized health services in all areas of the country. At present about a third of the population is without such service.
- b. To promote greater understanding of public health nursing as a service for everybody—regardless of size of income.
- c. To increase citizen participation in and support of public health nursing services.

d. To recruit public health nurses by encouraging nurses already trained to enter the public health field and by interesting high school and college girls to choose this work as a career; 8,000 more public health nurses are needed immediately.

e. To help relieve pressure on hospitals by making it generally known that part-time professional nursing care is available to people at home.

The N.O.P.H.N. has prepared a kit of materials for use during Public Health Nursing Week. It gives background material, suggestions for organizing local committees, for newspaper articles, radio talks, local proclamations, discussion group material, posters, and even comics. The kit is available from the National Organization for Public Health Nursing, 1790 Broadway, New York 19, at 50 cents. Ask for "How to Observe Public Health Nursing Week in Your Community."

AMERICAN WATER WORKS ASSOCIATION

At its annual meeting held in Chicago on January 13, the following officers were elected to serve for 1947-1948:

President—N. T. Veatch

Vice-President—Linn H. Enslow

Treasurer—William W. Brush

ALCOHOLISM IN THE NEWS

The New York Academy of Medicine recently made a survey of facilities for the care and treatment of alcoholism in New York City (published in the *Quarterly Journal of Studies on Alcohol*, December, 1946). Upon its completion the Research Council on Problems of Alcohol, sponsored an all-day meeting in New York City at which its findings were discussed. The Academy report was summarized by Hubert S. Howe, M.D., Chairman of the Subcommittee on Treatment Facilities for Alcoholics.

Among the facts brought out were that an average of more than 11,000 cases of acute alcoholic intoxication are annually admitted to New York

municipal hospitals, that the great proportion are discharged within 24 hours after sedative and sobering procedures only, and that few social agencies of the city have any constructive program for dealing with the problem.

The recommendations of the report, carried forward in resolutions of the conference, were for continued and co-operative action of such agencies as the New York Academy of Medicine, the Greater New York Hospital Council, the State and County Medical Societies, the Governor and the Legislature, the American Hospital Association, the American Medical Association, and the American College of Surgeons, in providing adequate facilities for study of the causes of alcoholism and for the treatment and cure of sufferers from it; also in developing minimum standards for the operation of such facilities; that alcoholism be recognized as an illness and treated in inpatient and outpatient departments of hospitals, and that a further conference be called of representative citizens in order to develop the public understanding required to meet the medical, legal and social problems of inebriety.

Following closely upon the Conference, the Research Council on Problems of Alcohol announced a grant of \$150,000 to the New York Hospital-Cornell Medical Center to finance a five year research project to get at the roots of the causes of alcoholism. This program is being undertaken as a pilot study to determine the most promising avenues to pursue in the fight against alcoholism. The research will be under the direction of Oskar Diethelm, M.D., Psychiatrist-in-Chief of New York Hospital. Patients will be hospitalized in special quarters. The Cornell project is one of several which the Research Council plans to establish in leading medical schools and their affiliated hospitals.

Other developments in the field of

alcoholism control are a recent announcement by the National Committee for Education on Alcoholism that there are now 19 local citizen committees in 11 states and Washington, D. C., to educate the public in understanding alcoholism as a public health problem. The most recent committee to be formed is in Rochester, N. Y.

In its recent annual meeting the National Jail Association, in resolutions, called upon the U. S. Public Health Service to earmark funds for the establishment of hospitals for the alcoholic and for state and local community programs for the control of this problem, and upon the Veterans' Administration to establish alcoholic wards in the general hospitals of the Administration.

In February the Columbia Broadcasting Company completed a weekly series of 13 coast-to-coast radio programs on "You and Alcohol" initiated because of what it conceived to be the growing importance of public interest in the medical aspects of alcoholism.

As to official activities, six states now have commissions for study of the problem of alcoholism. In Connecticut the work has progressed to the extent of setting up clinics for the treatment of sufferers in the city of Hartford. Six other states have legislative or other proposals which, if realized, will result in commission or other study in these states.

(For earlier discussion of alcoholism as a public health problem see Vol. 36 of the *Journal*, pp. 79, 545, and 925.)

CLINICAL FELLOWSHIPS OF AMERICAN COLLEGE OF PHYSICIANS

Following the end of the late war, the American College of Physicians resumed its research fellowships for the benefit of physicians in the early stages of preparation for a teaching and research career in internal medicine. In 1946 also some fellowships for medical officers discharged from service were

provided. The fellowships are designed to provide an opportunity for research training either in the basic medical sciences or in their application to clinical investigation. The stipend ordinarily is from \$1,800 to \$3,000, depending upon individual circumstances.

The first of the 1947-1948 fellowships has been awarded to Thomas F. Paine Jr., M.D., for continuing studies of infectious diseases, with special reference to chemotherapy and the use of antibiotics. His work will be done at the Thorndike Memorial Laboratory of Boston City Hospital. Dr. Paine was awarded a similar fellowship in 1946-1947.

Further information about the fellowships may be secured from the American College of Physicians, 4200 Pine Street, Philadelphia 4.

HOMER FOLKS RETIRES

The retirement of Mr. Homer Folks, Secretary of the State Charities Aid Association, New York City, was announced on the occasion of his 80th birthday, February 18, after a service of 54 years with the Association. As the dean of workers in the field of social welfare, Mr. Folks and his organization have been a part of every public health movement in New York State during the last half century, particularly in the organization of citizens' voluntary groups supporting tuberculosis efforts through the State Committee on Tuberculosis and Public Health, which in more recent years has included promotional services in the field of social hygiene, diphtheria prevention, and the organization of local health units.

Mr. Folks was Secretary of a special public health commission appointed in 1913 by the Governor of New York State which successfully urged the passage of a new public health law, important features of which have since been enacted in substance by a number

of other states. The law established the State Public Health Council and Mr. Folks has been a member and Vice-Chairman of the Council since its creation. In 1930 another special public health commission was appointed by the Governor, of which Mr. Folks was also a member. As a result of these studies a plan of state and district tuberculosis hospitals was adopted, and one of the hospitals was named for Mr. Folks at Oneonta.

Not only in public health, but in the field of mental hygiene, child welfare, and public welfare, Mr. Folks has been known in New York State and throughout the country. During World War I he organized and directed the Department of Civil Affairs of the American Red Cross Commission to France and served in Italy, Greece, Serbia, and Belgium during this period. Mr. Folks joined the American Public Health Association in 1912 and has been a Charter Fellow since 1922.

On March 1 Roland Burnstan, Ph.D., assumed his duties as Mr. Folks's successor. Economist, educator, and executive, he has most recently been president of the Lawrence Aeronautical Corporation and has served in the Minnesota State Planning Board and as a member of the League of Nations Committee to study the organization of peace.

PERSONALS

Central States

CHANGES IN HEALTH PERSONNEL IN KANSAS:

VIOLET KINSTLE, R.N., formerly Chief Orthopedic Nursing Consultant with the Kansas Crippled Children's Commission, Wichita, has accepted a position as coordinator to assist in the development of a new program in Muskingum County, Ohio. The plans for this new project include

physical therapy for crippled children in the public schools of Zanesville and a county-wide program for the care of the handicapped with special emphasis on cerebral palsy, parent education, and counseling.

HENRIETTA HANNA,† generalized Consultant Nurse with the Kansas State Board of Health for the last six years, has accepted a position as Nursing Consultant for the Division of Venereal Disease of the Illinois State Department of Health.

HAZEL ROSS-CRAWLEY, R.N., Field Nurse in the Division of Tuberculosis Control, Kansas State Board of Health, has resigned.

EVA BOURNE, R.N.,† who has been with the Douglas County Health Department since its organization in 1942, has been employed as Field Nurse in the Division of Tuberculosis Control of the Kansas State Board of Health.

ROBERT M. HEILMAN, M.D.,† resigned his position as Director of the Division of Industrial Hygiene, Kansas State Board of Health, and left the department February 1, to work in internal medicine on the staff of Winter Veterans Hospital. Dr. Heilman organized the Industrial Hygiene Division of the State Health Department in 1942.

DONALD HERNANDEZ † was recently appointed Assistant Sanitary Engineer by the DuPage County (Illinois) Health Department, Villa Park, Ill. Before attending the University of Michigan, Mr. Hernandez was employed for 8 months by T.W.A. on a malaria control project in Iran.

ROBERT S. INGOLS, PH.D.,* has been appointed to the faculty of the Georgia School of Technology, with the rank of Research Associate Professor of Sanitary Chemistry. Dr.

Ingols will work with Associate Professor GEORGE W. REID (Sanitary Engineering) on the recently announced \$20,000 program on water and sewage analysis, jointly sponsored by the U. S. Public Health Service and the School. He will also teach courses in sanitary chemistry as part of the training program for sanitary engineers. Dr. Ingols has most recently been instructor in public health engineering in the University of Michigan.

MARGARET C. LINDQUIST, R.N., has been appointed training assistant in Home Nursing, by the American Red Cross and is serving on the national nursing staff. Before joining the staff at American Red Cross, Miss Lindquist served as advisory nurse for the Minnesota State Department of Health.

ISABELLE MORGAN, M.D., will assume the duties of the Director of the Division of Maternal and Child Health, State Department of Health, Charleston, W. Va., beginning with February 1. For the past two years Dr. Morgan has been on the staff of the School of Public Health, University of Michigan, Ann Arbor.

LEONARD M. PRATT,† formerly Sanitary Engineer in District 3 Health Department in Michigan, and lately returned from a tour of duty with the Army Air Forces in the Philippines, is now Chief Sanitary Engineer with the DuPage County (Illinois) Health Department, Villa Park, Ill.

PHILIP G. RETTIG† has been appointed Director of Research and Legislative Services for the National Society of Crippled Children and Adults, with offices in Chicago. Mr. Rettig was a practising attorney of Chicago previous to his three years of war service as chief of the engineer intelligence branch on General Omar N. Bradley's 12th Army group staff.

Eastern States

THOMAS R. CAMP,* consulting engineer of Boston, announces the formation of a partnership with HERMAN G. DRESSER and JACK E. MCKEE to continue consulting practice under the firm name of Camp, Dresser, and McKee. The firm will specialize in water and sewage works and the treatment and disposal of municipal and industrial wastes. Mr. Camp was Professor of Sanitary Engineering at Massachusetts Institute of Technology for 15 years.

CHARLES M. CARPENTER, M.D.,* of the University of Rochester, N. Y., School of Medicine and Dentistry, has been granted a two months' leave of absence to direct a commission to survey certain aspects of the venereal disease problem in the Pacific Theatre for the Surgeon General of the Army.

WARD H. COOK, M.D.,* has been appointed to direct the laboratories at the Long Island College Hospital, Brooklyn, N. Y., when the expansion program of the hospital, now under way, has been completed. Dr. Cook has been Director of Bureau of Laboratories, Yonkers, New York, City, for the past 17 years.

WILLIAM A. DOPPLER, PH.D.,* has been appointed Executive Secretary of the New Jersey Tuberculosis League, Inc. He assumed his duties on April 1. Dr. Doppler has been a staff member of the National Tuberculosis Association, New York, N. Y., since 1935, first as Field Consultant in Health Education, later as Director of Industrial Relations.

L. WHITTINGTON GORHAM, M.D., Albany, N. Y., has been designated by Governor Dewey as Chairman of the State Public Health Council succeeding the late SIMON FLEXNER, M.D. Dr. Gorham is Physician-in-

* Fellow, A.P.H.A.

† Member, A.P.H.A.

Chief of the Albany Hospital, a member of the executive committee of the S.C.A.A. State Committee on Tuberculosis and Public Health, and of the Health Education Committee of the Albany Tuberculosis Association.

GERTRUDE HESS, R.N.,[†] formerly with the Henry Street Visiting Nurses Association, New York, N. Y., has been appointed by the DuPage County (Illinois) Board of Health, Villa Park, Ill., as Director of Nursing and Health Education for the DuPage County Health Department.

ROSCOE P. KANDLE, M.D.,* Director, Bureau of Preventable Diseases, New Jersey State Department of Health, has succeeded CECIL K. BLANCHARD on the State Board of Examiners of health officers and sanitary inspectors. Mr. Blanchard retired on January 31, 1947, from his position as Supervisor of District Health Officers and Sanitation after 34 years in the department. With his retirement will be discontinued also "Mark Time," his column in *Public Health News* of the New Jersey State Department of Health.

JOHN N. McDONNELL, M.D.,[†] has been appointed vice-president of the Schering Corporation, Bloomfield, N. J. Through the war years, Dr. McDonnell headed the drug research and civilian penicillin distribution units of the War Production Board.

ROBERT E. PLUNKETT, M.D.,[†] formerly General Superintendent of New York State Tuberculosis Hospitals, has assumed his new duties as Assistant Commissioner for Tuberculosis Control of the State Health Department. As such he will be largely responsible for the fulfillment of the state's expanded tuberculosis control program, the main objective of which is to blot out tuberculosis in New York by 1965.

MARY E. SPENCER, Ph.D.,* has been appointed chief of the Bureau of

Health Information of the Massachusetts Department of Public Health. Dr. Spencer is known for her work as Director of the Health Education Bureau of the National Welfare Conference in Washington, D. C., representing the United States at the World Federation of Education Association at Geneva. She also served on the Hoover White House Conference on Child Health and Protection. She is vice president of the Massachusetts Public Health Association and Life Member of the A.P.H.A.

HERMAN WEISKOTTEN, M.D.,* Dean of the Syracuse University School of Medicine since 1925, has been elected chairman of the Council on Medical Education and Hospitals of the American Medical Association. Dr. Weiskotten is the author of *Medical Care of the Discharged Hospital Patient* and of *Medical Education in the United States, 1934-1939*, the findings of a survey of the medical schools of the country.

Southern States

N. G. ANGSTADT, M.D.,[†] Director of the Bureau of County Health Work, State Department of Health, Charleston, W. Va., resigned, effective January 1. Dr. Angstadt has accepted the position of Medical Director for the Public School System of Reading, Pa.

BURTON F. AUSTIN, M.D.,[†] after 26 years of public health work in Alabama and serving as head of the State Health Department since 1942, has resigned to take up new duties as Southeastern Regional Medical Director of the American Red Cross with headquarters in Atlanta, Ga.

BERTRAM M. BERNHEIM, M.D., Associate Professor of Surgery at the Johns Hopkins Medical School, Baltimore, Md., has received the third annual Norton Award of \$3,500 for his book *A Surgeon's Domain*. The

award is made annually by the Norton Publishing Company for the best book by a professional man written for laymen.

MAYHEW DERRYBERRY, PH.D.,* Chief of the U. S. Public Health Service's office of Health Education, Washington, D. C., has been assigned temporarily to serve as Consultant in Health Education with the American National Red Cross. Dr. Derryberry, at the request of the Red Cross, will study its present health education services for the purpose of evaluating and coördinating programs now in operation. He will also advise with G. FOARD MCGINNESS, M.D.,* Red Cross vice chairman for Health Services, on possible future health education activities of the national organization.

JAMES M. FREEZE, M.D., has been appointed Director of the Alabama State Health Department's Division of Tuberculosis Control. He succeeds N. H. DEJANNEY, M.D., resigned.

J. ROY HEDGE, M.D., recently resigned as District Director of Local Health Service in the North Carolina State Health Department to become Health Officer of Cabarrus County, with headquarters in Concord, N. C.

ELLA MAE HOTT, R.N.,* has joined the American National Red Cross Nursing staff as Assistant Director of home nursing. Before going with the Red Cross, Miss Hott was director of the Division of Public Health Nursing for the Missouri State Board of Health.

J. D. STILLWELL, M.D., from the regional office in Waycross, Ga., has been transferred to the State Health Department in Atlanta, as Assistant Director of Local Health Organizations. He replaces H. M. GRANING, M.D.,* assigned to Georgia by the U. S. Public Health Service, and recently recalled by the Service for assignment to Cancer Control Activities.

Western States

CHANGES IN CALIFORNIA STATE DEPARTMENT OF HEALTH:

GEORGE T. PALMER, DR.P.H.,* has been appointed Consultant in Public Health Administration, Division of Administration. Dr. Palmer has served with the Detroit and New York City Health Departments and with the American Public Health Association. He comes to the department following an assignment with the U. S. Public Health Service.

J. WALTER HOUGH, M.D., has been appointed Medical Officer, Bureau of Adult Health. Dr. Hough is on loan from the U. S. Public Health Service. Before joining the department he served with the Oklahoma Health Department.

MARION JOSEPHI, M.D., has been appointed Consultant in Rheumatic Fever, Bureau of Maternal and Child Health.

JOSEPH A. MOORE, M.D.,† has been appointed Acting Chief, Acute Communicable Disease Service.

YOSHIYE TOGASAKI, M.D., has been appointed Medical Officer, Bureau of Maternal and Child Health.

EVELYN SPRAGUE has been appointed Industrial Nursing Consultant, Bureau of Public Health Nursing.

J. M. BURNETT, M.D., assumes the duties of Kittitas County Health Officer, Washington, on March 3, 1947.

S. J. HATHAWAY, M.D., has been appointed Acting Health Officer of Yakima County-City Health District, Washington, during the absence of STANLEY BENNER, M.D.,* Yakima County-City Health Officer.

EDWARD GAGE TITUS, Sc.D., was appointed Director of the Division of Vital Statistics of the Utah State Department of Health in December,

* Fellow, A.P.H.A.

† Member, A.P.H.A.

1946, after serving as statistician in the department since February, 1943.

Foreign

F. KENNETH ALBRECHT, M.D.,† has joined the Editorial Department of the Williams & Wilkins Company, medical publishers of Baltimore, Md. Dr. Albrecht has been associated with the U. S. Public Health Service with the rank of Surgeon.

Death

INA M. GASKILL, R.N., died in Indianapolis, Ind., January 13, 1947, following a long illness. In 1919 Miss Gaskill was employed by the American National Red Cross to develop rural public health nursing services throughout Indiana. Working with the State Department of Health, she demonstrated the need for a bureau of public health nursing and became its first director in 1921.

Maternity and Child Welfare in a Large British City*

JEAN M. MACKINTOSH, M.D., D.P.H., D.P.A.

*Senior Assistant Medical Officer for Maternity and Child Welfare,
Birmingham, England*

BEFORE describing the work of my department I think it would be well if I gave some factual information for the benefit of those who are not very familiar with the British background.

Although Great Britain is no larger in area than a medium sized American state, approximately 45 million people live there. There is no part of the country which does not come within the purview of an organized health department. Each of these departments is under the control of a whole-time medical officer who has had postgraduate training in public health. For all practical purposes there are only two levels of government—central and local—as opposed to three in the United States.

Except in some of the lower grades all central and local government employees have security of tenure and are pensioned. The contribution made by voluntary funds to public health services is infinitesimal compared with the United

States. All the activities of public health departments are paid for out of tax funds, either central or local. The proportion which comes from central funds may vary from 20 to 60 per cent and is based on a complicated formula which takes into account the amount of unemployment in the area, the birth rate, and other factors.

I might say here that, although the local authorities receive subsidies from the central exchequer, there is no suggestion that dictation of policy comes from the center. Indeed there are occasions when quite the contrary is the case. I think it would be true to say that no legislation is put up by the central government for consideration by Parliament without prior consultation with the local authorities and, indeed, these local authorities may themselves suggest to the central government legislation which they think desirable. There are occasions when the central government and the local authorities are unable to reach agreement on main principles but these are rare. When this occurs the matter is argued out in Parliament and a compromise is usually reached. Since 1930, the medical officer

* Presented before a Joint Session of the Maternal and Child Health, Public Health Nursing, Dental Health, and School Health Sections of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 13, 1946.

of health for the larger local authorities has had administrative charge of all general and contagious diseases. The new plan for a National Health Service is going to alter this situation in certain ways but that is outside the scope of this discussion. Local authority health services are available to all citizens regardless of income. In certain instances there is recovery of cost, or a proportion of the cost, according to the ability to pay.

Birmingham is a city of a million inhabitants and is the center of a great industrial area. The city occupies 51,147 acres. It is surrounded, especially to the north and west, by densely populated areas. Situated in a rich coal and iron region, it has increased greatly in importance and size during the last 100 years. This rapid expansion took place in the early years without any organized planning, and has left the city a legacy of bad housing, cramped streets, and overcrowding. Before the outbreak of war 50,000 houses were being considered for demolition. During the war 14,219 dwellings were totally destroyed by enemy action and 111,245 others were damaged. Before the war there were approximately 300,000 dwellings in Birmingham; 55,000 houses were owned and rented to citizens by the City Council. During the past year 1,356 houses have been erected, 232 by private enterprise and 1,124 by the City Council. In a similar period after the first World War only 826 houses were erected compared with 1,356 on this occasion. Birmingham is a city of a thousand trades in contrast to many other cities in Great Britain which are wedded to one type of industry. As a result Birmingham has an economic resilience which many cities lack and, in consequence, did not suffer the worst effects of unemployment during the years between the two wars.

The Maternity and Child Welfare branch of the Health Department is

primarily concerned with the care of the expectant and nursing mother and of the child up to the age of 5 years who is not in attendance at a nursery school. The care of children in the nursery schools and the public schools is the responsibility of the School Medical Department which, in Birmingham, is a separate department from that of the Medical Officer of Health. This arrangement is exceptional. In most parts of Great Britain the Medical Officer of Health is also in charge of the School Medical Department.¹

My staff consists of 20 whole-time medical officers, 35 part-time medical officers, 118 whole-time, fully qualified public health nurses, 130 nurse midwives who deliver women in their own homes, and the medical and nursing staffs of four maternity units and a babies' hospital for children under the age of 5 years. We have 32 child health centers or stations. In addition we have 6 residential nurseries and 50 day nurseries providing accommodation for 2,500 children under 5 years of age. During the war we had 75 day care nurseries caring for 3,500 children. These nurseries are for children whose mothers go out to work, are ill, or for some other reason are unable to give the children adequate care. The total number of staff attached to these nurseries at the present time is 730.

The annual expenditure out of public funds on public health in Birmingham including expenditure for hospitals and tuberculosis, is approximately 6 million dollars. One-third of this amount is spent on maternity and child welfare services. This includes some expenditure for hospitals. If hospital expenditure is excluded, the annual cost to public funds of providing a domiciliary midwifery service is \$160,000, and of the other activities of my department \$1,200,000. The cost of the school medical service is \$290,000. The school lunch service costs the city \$951,000.

To put it another way—the total expenditure of the Public Health Department, including expenditure on hospitals and tuberculosis, is approximately \$6 a person. (This does not include the cost of the school medical service.) This breaks down into a little more than \$4 a person for all hospital services, including tuberculosis and maternity care, and something less than 20 cents a person for the domiciliary midwife service. The cost of the maternity and child welfare service, exclusive of the hospital and midwife services mentioned above but including the cost of child health stations, added to the cost of the school medical service, comes to about \$1.50 per person.

In describing the work of the department I would like to begin with the pregnant woman who wishes to make arrangements for her confinement. She has three courses open to her:

1. She may engage a private doctor to attend her either in her own home or in a nursing home. If she decides to have the doctor attend her in her own home, she can engage either a private nurse midwife or one of the nurse midwives employed by the department who, in this case, would act as a maternity nurse and work under the direction of the private doctor. (Approximately 50 per cent of the women confined in Birmingham are delivered in their own homes. Only 20 per cent of these have a doctor in attendance.)

2. She may engage only a city nurse midwife and have her baby in her own home. In this event, the nurse midwife is responsible for the patient and a doctor is called only when necessary. In only 5 per cent of the cases where a nurse midwife is responsible for the confinement did she consider it necessary to call a doctor to assist her at the confinement.

3. She may elect to be confined in one of the hospitals in the city. Owing to the great shortage of maternity beds at the present time, this may not be possible. Admission to hospitals has to be strictly limited and certain cases must be granted priority. Maternity hospitals are staffed throughout with nurse midwives or nurse midwives in training.

In either of the last two cases the

mother will attend a prenatal clinic either at the hospital or at one of the Maternity and Child Welfare Centers in the city. The clinic is staffed by a doctor, public health nurses, and nurse midwives. The doctor is either a whole-time or a part-time employee of the City Council, and has special qualifications for this work.

If the patient's home is far from the hospital of her choice at which arrangements have been made for her admission, she attends a prenatal clinic at the nearest Child Welfare Center until the 28th week of pregnancy, when she is sent to the hospital clinic with a cooperation form giving full particulars of her progress. This gives the doctor who is to be responsible for her delivery an opportunity of examining her. Thereafter, unless there is some special abnormality, she continues to attend the Child Welfare Center clinic until the 36th week, when she returns to the care of the hospital clinic.

If the mother intends to have her baby at home and has engaged a city nurse midwife she continues to attend the district prenatal clinic, her nurse midwife being present at each examination.

During the war, owing to the difficulties of transportation, shortage of staff, black-out conditions, etc., the nurse midwives were unable to give adequate prenatal care to their own patients and more and more of the examinations, which the midwives are quite capable of performing, had to be made by the doctors at the clinics. It is not considered desirable that this practice should continue. In consequence, now that the war has ended and the shortage of staff is slowly abating we propose to make some new arrangements whereby the nurse midwives will hold their own prenatal clinics at Child Welfare Centers and refer cases from there to the doctors' clinics. We also have an emergency service for domiciliary midwifery cases

which makes the services of a consultant and a blood transfusion outfit immediately available in the patient's own home on the call of the doctor. Except where the patient has made her own private arrangements, payment for these domiciliary services is made by the city to the doctors concerned. Thereafter recovery of expense is made from the patient according to her means.

You will see from this account of our midwifery services that the nurse midwife occupies a much more important place in Great Britain than she does in either the United States or Canada. With us she is an independent practitioner. The great majority of nurse midwives in Great Britain are fully trained state-registered nurses who take midwife training after completing their general training. A state-registered nurse who wishes to become a fully qualified midwife must take a year's additional training. Other women who wish to become fully qualified midwives, and who do not have the training of a state-registered nurse, must train for a period of 2 years. The majority of these nurse midwives are in salaried appointments. In Birmingham, for example, only 10 per cent of the nurse midwives in domiciliary practice are in independent practice.

Apropos of this, it is interesting to note that our figures in Birmingham for maternal deaths, stillbirths, and neonatal deaths are as good as any similar figures obtained for cities in this country. In the present state of our knowledge it is believed that 39 per cent of these maternal deaths were avoidable. I wish I could say that our record for infant deaths between 1 month and 1 year were as good. In that age period we are far behind what has been attained in the United States. Our lowest infant death rate in Birmingham was 42 in 1944, of which approximately half occurred after the first month of life.

It is not enough to make arrangements for the mother. The family too may need assistance during the period of the confinement. Here too we come to their aid. If the expectant mother is to be confined in a hospital, and if she is unable to make private arrangements for her family, the other children may be admitted to a residential nursery operated by the department for the period of her stay in hospital.

Whether the mother is confined at home or in a hospital she may be in need of domestic assistance in her own home. This the Maternity and Child Welfare Department supplies through its Home Help Service, or as you would call it—the Homemaker Service. The Home Helps are usually middle-aged women, married or single, who have an aptitude and liking for domestic work and children. They receive a short training, which includes some instruction in cooking and housework and the feeding and care of children. When not engaged on a case they are paid a retaining fee of 50 per cent of their normal wage. The vast majority are daily workers who go into the home from 8 a.m. to 4:30 p.m. each weekday. Recently we have begun the experiment of residential Home Helps. During the war this service fell to a very low ebb but recruitment is now going on steadily. When I left we had a staff of 110 of these women but we could do with many more.

Notification of all live and stillbirths are sent to the Medical Officer of Health by the nurse midwife or doctor within 36 hours of delivery. The midwife continues to attend the mother for a fortnight either at home or in the hospital. As soon as possible thereafter the mother is visited in her own home by a public health nurse. The public health nurse in Great Britain is a fully trained state-registered nurse who has had in addition 6 months' training in midwifery and 6 months' training in public health

nursing, each period of training being followed by an examination. The great majority of public health nurses do educational and preventive work only and do not engage in bedside care. In scattered country areas however, they may combine their public health work with bedside care.

The public health nurse gives advice to the mother on the feeding and management of her baby and invites her to attend the child welfare clinic. At her first attendance, the mother, unless she has previously been examined in a hospital, is given her postnatal examination, as well as advice about her baby. The services of the public health nurse are available to every mother in the city. In fact, in Birmingham in 1945 the public health nurse visited 91 per cent of the infants born in that year. Eighty per cent of the children visited in their first year attended the Child Welfare Centers. Half of our 32 Child Welfare Centers are in buildings erected for the purpose; the others are in converted buildings used solely for that purpose.

The mother is encouraged to bring her baby to the Child Welfare Center at regular intervals up to the age of 2 years. After that the child attends a toddlers clinic which is run on the lines of a school medical inspection and receives a full physical examination every 3 months. Attendance at these clinics is by appointment and they are becoming increasingly popular among young mothers. In the interval between these appointments mothers are at liberty to take their children to the ordinary child welfare conference.

Other activities are also carried on at the Child Welfare Centers, such as, diphtheria immunization clinics, ultraviolet light clinics, remedial exercise clinics, sewing classes, cookery classes, etc. At other sessions talks on the various aspects of parent-craft are given to the mothers. Dental care is given to

mothers and children. Dentures are also provided when required for the mothers.

A special feature of the work in Birmingham is the care of the unmarried mother and her child. In 1945, 9.2 per cent of total births were illegitimate. Thirty-three per cent of these infants were born to married women. We have three public health nurses especially assigned to deal with this work. Over 90 per cent of the women in the city who are illegitimately pregnant come to our department for assistance. We arrange accommodation for them before their confinement, either in a home for unmarried mothers or in private lodgings. If the mother is in poor financial circumstances we assist in the payment for these lodgings. We arrange for her delivery and, if need be, we place the mother and baby in lodgings after delivery to give them an opportunity to get on their feet. Thereafter we give special care to the baby until it is 1 year old. As a result of this, twice during the past 5 years the infant death rate for the illegitimate child has been lower than the infant death rate for the legitimate child.

We also exercise supervision over children up to the age of 9 years who are boarded in private homes by their parents or relatives. We have a program whereby the foster mothers are subsidized by our department. We found that the type of woman engaged in this work was not very good, because of the precarious financial return. The unmarried mother could not always be relied on to pay her way. Under our program the foster mother is paid directly by the department and the mother of the child is asked to pay to the department what she can afford toward the child's maintenance. We find that the mothers respond well to this arrangement and that they repay as much as they can afford. When the program was started in March, 1935, the net weekly cost per child to the

city was \$1.10. In 1945, the net weekly cost per child was 23 cents. During the war years the economic circumstances of these women improved and in consequence they were better able to meet their responsibilities. We also deal with 71 per cent of the children who are placed for adoption in the city, arranging full medical examination for them and their adopting parents.

It is not possible here to deal fully with the many other aspects of the work undertaken by my department. I can only mention in passing our training school for public health nurses, which we run in collaboration with the university, and which takes 50 students each year; the work which the health visitors undertake as part of the general health education program in the schools, the youth clubs and adult organizations; our supervision and operation of day and residential nurseries, and our supervision of private nursing homes and nurse hiring agencies.

Lastly, I must say a word about the Child Health Institute. For a long time we in Great Britain have felt that there has been too great a gulf between the curative and the preventive sides of pediatrics. In consequence a number of Child Health Institutes have been set up throughout Great Britain in association with the universities. The type of organization varies from place to place. In Birmingham we hope we are going to be able to achieve the perfect marriage between curative and preventive pediatrics.

The Child Health Institute in Birmingham is as yet merely an organization and not a concrete building. Whether its activities will ultimately be housed in one building remains to be seen. At the present time they are carried on at the Children's Hospital and one of the larger welfare centers. The Institute is managed by a Council which consists of the following members:

The Vice Chancellor of the University
The Professor of Child Health
A member of the Medical Board of the Children's Hospital
Two lay members of the Board of the Voluntary Children's Hospital
The Professor of Social Medicine
The Professor of Obstetrics and Gynecology
The Medical Officer of Health
The Senior Medical Officer for Maternity and Child Welfare
The School Medical Officer
The Tuberculosis Medical Officer
Two members of the Public Health Committee of the City Council
Two members of the Education Committee of the City Council
A member of the British Medical Association

It is staffed by:

1. *A whole-time Professor of Child Health* who is allowed to carry a limited amount of private practice. He is appointed and paid by the university, and the conditions of his appointment and the amount of his remuneration are settled by the university. By virtue of his position as Professor of Child Health he is a physician on the staff of the Children's Hospital and as part of his duties is available when required to act as a consultant in the child welfare service.

2. *Readers*—These are two in number and of equal standing. One gives part-time service and is a local authority medical officer who supervises the training of undergraduates and postgraduates in the preventive aspects of child health. At the moment I act in this capacity. The other Reader is a physician in the whole-time employ of the university and is paid by them. He is also on the staff of the Children's Hospital. The rate of his remuneration is fixed by the university. He acts as assistant to the Professor in all branches of the work except the organization of that part of the teaching which deals with the preventive aspects of child health.

3. *Lecturer in Child Health*—This is a part-time appointment. The lecturer is a member of the local authority staff

who, under the direction of the Reader, gives lectures on various aspects of child welfare to undergraduates and post-graduates. In addition, she acts as medical officer to out-patients $\frac{1}{2}$ day a week at the Children's Hospital and has opportunities to follow up the cases seen there in the wards. For this reason she is designated as a clinical assistant.

4. *Physicians*—These physicians are 4 in number. They are on the staff of the Children's Hospital and engage in private practice. They will also be available for consultation in the child welfare service.

5. *Clinical Assistants*—In addition to the lecturer in child welfare, certain whole-time medical officers of the local authority attend $\frac{1}{2}$ day a week at the out-patient department of the Children's Hospital. In addition, they spend $\frac{1}{2}$ day a week in the wards of the Children's Hospital.

6. *Registrars*—These officers are 4 in number and are on the staff of and paid by the Children's Hospital. They each act as medical officer at two child welfare conferences a week, in the local authority service as part of their normal duty and without additional remuneration.

The plan is financed by the university, the City Council, and the Children's Hospital. These three bodies bear the cost equally between them. It is estimated that the annual operating costs will be in the neighborhood of \$60,000. The Institute aims to improve and extend the knowledge of undergraduates and postgraduates in all aspects of preventive and curative pediatrics and to promote research as well as to raise the level of child care in the area.

In conclusion I have been asked to say a few words about what I think the impact of the new National Health Service on the present maternity and child welfare service is likely to be. The first thing that will happen is that

the maternity hospitals will cease to be the immediate concern of the public health department. It is not intended, however, that there shall be a sharp division between hospital and domiciliary midwifery practice, but rather that there shall be coördination and correlation between the two.

It has been said that the family doctor will take over the work of maternity and child welfare departments. If this happens at all, which I very much doubt, I think it will take at least ten years to bring it about. The term "family doctor" is an example of the modern tendency to use a word or phrase sometimes as an anesthetic, sometimes as a bogey man. It is nowhere suggested in the National Health Service that a wife must of necessity have the same doctor as her husband. Indeed it has been said that when group practice is set up in health centers certain practitioners will specialize, for example, in pediatrics. Either situation is incompatible with the term "family doctor." The type of educational work being undertaken by medical practitioners at child health stations has not so far been taught in any great degree to undergraduates, although a beginning has been made. Neither are our pediatricians, in Britain at least, as yet fully cognizant of the preventive aspects of their work. For these reasons I think the discontinuance of our work during the next few years is, to say the least, unlikely. It may gradually evolve into something else, but that is another matter.

The National Health Service Act also requires local authorities to organize a nursing service for bedside care. This immediately brings up the question of what should be the extent of a generalized nursing service. Opinions are sharply divided about the matter in Great Britain, at the moment, and I cannot venture to predict what the outcome will be. All I can say is that as

far as the Maternal and Child Health Services as a whole are concerned, I feel that far from diminishing in importance they are likely in the future to

make an increasing contribution to the welfare of the nation as a whole.

British Representation at the 75th Annual Meeting

Great Britain will be well represented at the 75th Annual Meeting of the Association in Atlantic City. Both Sir Andrew Davidson, Medical Officer of Health of Scotland, and Sir Allen Daley, County Medical Officer of Health of the London County Council, have been invited to speak before the Health Officers Section. In connection with his visit to the United States, Dr. Daley will visit a number of cities and schools of public health to study the administrative procedures that result in low infant mortality and tuberculosis death rates and to study American methods of training public health officers.

The Royal Sanitary Institute will

send two official representatives to the meeting: F. T. H. Wood, O.B.E., M.D., O.P.H., who is chairman of the Council of the Royal Sanitary Institute and Medical Officer of Health of Bootle, Lancashire; and Charles Porter, M.D., M.R.C.P. (Edin.), who is past chairman of the Council and vice president of the Institute and a retired Medical Officer of Health.

Also planning to attend the Atlantic City meeting is Dr. R. Sutherland, Medical Secretary of the Central Council for Health Education and editor of the quarterly, *Health Education Journal*. He will visit a number of health education activities in the United States.

Regulation of Housing: Hints for Health Officers*

CHARLES S. ASCHER, LL.B.

*Formerly Regional Housing Expediter, Office of the Housing Expediter,
New York, N. Y.*

I SHOULD like first to come to an agreement with the health officer about the use of certain legal phrases which I am certain have often befuddled him in his dealings with the city attorney or in his appearances in court. I should like to put into their legal setting the ideas that this paper is to discuss.

The regulation of housing is an application of the police power, the power of the community to insist that an individual limit his freedom of action in the paramount interest of the community, without compensation. Fortunately, under our Anglo-American system of law the courts have steadfastly refused to stake out the boundaries of that power. In the classic words of Justice Holmes, it is defined by the pin-pricks of conflicting decisions—a process admittedly not intellectually satisfying to a scientifically trained mind, but one that has certain advantages in the resolution of conflicts between individual liberty and social controls.

Holmes, in another decision, outraged even the lawyers who like to rest intellectually in neatly defined and rigid categories by saying that the police power was whatever the community preponderantly desired at a given time. Without being a lawyer, the health officer must have observed within the

span of his own professional career that he can today obtain public and judicial backing for controls that he could not have dreamed of exercising several decades ago. One of the topics I should like to discuss is the reason for this progressive change as a lawyer and administrator would analyze it.

There is another power of the state, the power of eminent domain, sometimes called condemnation. (This must be distinguished from "condemnation" as the health officer uses it in speaking of the enforced destruction of decayed meat. That, it will readily be seen, is an exercise of the police power.) The power of eminent domain is the power to take a man's property or limit his use of it in the paramount interest of the community with just compensation. The line is shadowy between those acts of control for which a legislature and a court will say that the community should pay and those upon which it may insist without compensation. Not only is the line shadowy, it moves.

The early history of the control of the height of buildings is an account of the attempt to buy from property owners the right to build above the socially desired height. After a few tries in which the legality of the use of eminent domain for this purpose was upheld by the courts, people got restive. The approach seemed rather like the economy of the famous village of Ballycannon where everyone made a living taking in everyone else's wash. So the public said simply, "We will forbid—"

* A paper read at a training course in housing for health officers sponsored by the School of Public Health, University of Michigan, Ann Arbor, August 27-29, 1946. Printed by permission of the School of Public Health.

and the courts upheld the action. Oddly enough, the economics of land works out so that the value of land quickly adjusts itself to an intensity of use based upon the legally permitted height of buildings.

It is also instructive to note that the friends of this form of control—it is one of the elements of zoning—deliberately avoided bringing a test case to the highest court for nearly ten years. They yielded here, they compromised there. But when the Ambler Realty Company protested the control of its land by the Village of Euclid to the United States Supreme Court, Justice Sutherland, no flaming radical, could uphold the new exercise of the police power in a broad, ringing opinion in which one of the chief arguments was, forsooth, that more than 25,000,000 people were living in 366 zoned municipalities as against fewer than 11,000,000 people in 48 zoned cities and towns five years before. This effective use of statistics was a favorite technique of Justice Louis Brandeis in his arguments before the Supreme Court as a practising attorney. It was a new approach couched in scientific and sociological terms.

The argument that so large a segment of our population was then living under the beneficent influence of zoning was a cogent one which the United States Supreme Court could not ignore. This approach is a lesson in major strategy that might well be mastered by health officers for use in campaigns in theaters other than zoning and housing.

Centuries ago, long before our Constitution was written and the body of American constitutional law was developed by such free minds as Holmes and Brandeis, courts recognized that an owner's use of his property could be to the detriment of others, particularly neighboring property owners. Indeed, a Latin tag was established as a principle of the medieval law of land: use

your property so as not to injure another. Even a court dedicated to the sanctity of property rights could easily concede that, although your home was your castle, you could not let raw sewage flow over onto the land of an owner down the hill; you could not dig an excavation that would undermine your neighbor's house. Such a court was ready to restrain uses of land that offended the neighbors' senses of smell and hearing: a tannery set up too near homes; a stamping mill that shook the dishes on neighbors' shelves—these were "noisome," they were "nuisances," they could be "abated" at the suit of the outraged neighbor.

Many health officers have a notion that their strength lies in persuading the courts that something against which they want to proceed is a nuisance. I am one of a group of lawyers who are convinced that there is no future to the doctrine of nuisance, for several reasons. First of all, some of the uses of land and buildings that you want to control are not "noisome," they are just in the wrong place. No one could claim that they are illegal *per se*, indeed they may be necessary for the community. But in a well ordered city the public should be able to prescribe the proper location for them. That is not the same as saying that they are offensive or noisome or a nuisance.

Second, the body of legal doctrine on the abatement of nuisances was evolved before the germ theory of disease was accepted. There was, therefore, no special expertness, there were no objective factual data with which a group of persons like health officers could claim special or exclusive competence to deal. Their appearances in court were as purveyors of opinions to be pitted against the opinions of others. There was no valid reason to prevent a court from substituting its judgment for that of an opinion witness in its eagerness to assure the protection of property rights.

Thus, in a 19th century leading case, the highest court of New York was asked to pass upon evidence consisting of "statements of competent persons under oath that the business endangered the health of the people of the vicinity, was offensive to the senses, and rendered their life uncomfortable." (In that case, moreover, the municipal official had first issued the order to abate the nuisance and the property owner had been given a hearing after the official act, not as a basis for deciding whether to take official action.)

The doctrine of nuisance is not a profitable one through which to move forward with housing regulation. To try to bring about a series of judicial redefinitions of nuisance is not a realistic way to bring modern standards of health and housing expertness to bear upon the elimination of substandard dwellings.

I have thus far suggested that neither eminent domain nor the common-law doctrine of nuisance is the basis for the regulation of housing by health officers and housing officials and city planners; we must look to the police power for our base. I have thus led the health officer to the edge of a most fruitful field, from which, however, I find that health officers tend to shy away.

There are in our society many other forms of limitation of the action of the individual in the interest of the community. Scientists other than medical men have worked with lawyers in evolving modes of enforcement that achieve the goals of the scientist while still preserving adequately the rights of the individual. Why should we not look at the tools they have forged, why should we not analyze our problems using the calculus that they have devised, to see how we can restate our purposes in such terms as to take advantage of the progress made in other fields? There seems to be no reason. Yet, I have seen

a group of the ablest health officers completely baffled when I have said that there was something to learn from the U. S. Steamboat Inspection Service, or the Immigration and Naturalization Service: what problems, pray, could they have that had any meaning for healthful housing?

There is a group of men to whom I urge you to turn for help. They are the catalysts, the specialists in evolving modes and procedures that balance community interest and individual rights in ways that gain acceptance in the courts. They are called administrative lawyers. There are not many of them among the larger group of lawyers, or even of municipal lawyers. I am not one of them, but I know them and I have gained respect for the importance of what they have to offer those seeking to advance the service state, to obtain support for the government that seeks to protect its citizens and bring to social living the findings of modern science.

Their formulations seem annoying to the scientifically trained public officer who knows he is right and knows what ought to be done. It does not seem to make sense to throw the enforcement case out of court, when the property owner had actual notice of the alleged violation, merely because the ordinance under which the health officer was acting did not require notice. The owner was in the wrong and he knew perfectly well what was wrong. Nevertheless, I have had to say to friends in the U. S. Public Health Service: "If you want to put people in jail, you'd better listen to my administrative law friends. Do you want to put people in jail or don't you?"

And I have had to assuage the feelings of one of the ablest health officers in the country—a leader in seeing the importance of good housing for health—the health commissioner of a large eastern seaboard city. He tells me of a flagrant violation of healthful housing,

an open sewer backing up in a cellar. He tells of the months lost in the search for the legally responsible person, while one defendant after another wiggles out of his grasp, by asserting that he is only agent or former owner. When the owner is cornered, his attorney obtains continuance after continuance. A year later, the health officer finally confronts the owner in court, having wasted the taxpayers' money in half a dozen unnecessary reinspections. He introduces in evidence the photographs, which reek with a stench that reaches even a judge's nostrils. "Do you mean to say this condition is allowed to exist?" "Well, your Honor," says the inspector, "just last week on the eve of this trial the owner made a half-hearted attempt to correct this condition, so that its worst aspects have been modified." "Then what are you doing here? You got what you wanted, didn't you? Case dismissed," thunders the judge. And I have to persuade the Commissioner of Health that this disposition of the matter is just about the verdict that any jury of twelve average reasonable Americans would bring in. The owner complied, didn't he? Sure, it took him a while and he stalled around. But we won't put him in jail for that.

Rightly seen, enforcement is one of a series of tools of the administrator as agent of society to bring about conformity with socially desired standards. His task is always to balance or blend education, persuasion, coercion. He must recognize honest attempts to conform which are within a range of tolerance. That tolerance point must be explainable to the average citizen, the legislature, and the courts.

The administrative officer must, therefore, first develop from the body of scientific knowledge a set of principles within the scope of public understanding and support. He must then make a particularized set of rules to guide enforcement that will make clear

the standards to be imposed. There must be artistry in taking into account sources of opposition, in adapting proposals to opponents' criticisms before test cases arise to unsettle basic authority and power. (Recall what I said about *Ambler vs. Euclid*.)

Note that I have several times in the last paragraphs emphasized *standards*. Let me elaborate the significance of standards for the objectives we all have in view. Only by developing objective scientific criteria to measure whether a dwelling is substandard have we provided any basis for raising the place of the health officer above that of another purveyor of opinions. And in a contest of opinions, the judge, being human, will deem it entirely proper to substitute his opinion for that of anyone else in the case. He has the last word, hasn't he?

If we can confront the judge with skillfully marshalled classes of data about which he cannot question, even to himself, the competence of the specialist to express that final opinion, we have put him in a position where he can gracefully, and without lowering the dignity of the bench, rely on the evidence of the scientist and upon the will of the people as represented by the acts of their legislative bodies. It is in such cases that we get these beautiful declarations of recognition of limitations of judicial power. "Ours is not the task of saying whether the ordinance is wise: that is the task of the city council. We cannot say that they lacked a foundation for believing the regulation to be necessary. And the defendant has not presented evidence to show that the health officer did not correctly apply the rule in this case in conformity with procedures that gave the defendant an opportunity to be heard before official action was taken against him."

This status of finality of findings of fact in regulations of public health can be attained for administrative action in

the field of housing. This is a necessary step in the emergence of standards of administrative legality. As these standards are increasingly observed in the practical work of the government housing agencies, judicial review will take a more and more constructive turn.

It can be won only as scientists develop objective, scientific criteria. Those criteria may apply to the structure or its structural parts to its relation to its surroundings and its life maintenance and to the neighborhood of which the dwelling is a part even though the building is not structurally falling apart. Collapse is not essential to establish substandard housing. There must be new criteria for what is substandard.

It is to the development of those scientific criteria that the Subcommittee on the Hygiene of Housing of the American Public Health Association has devoted itself for nearly a decade. Other articles in this JOURNAL have reported its notable achievements,¹ about which I can boast because, although a member of the committee, I have had no hand in that part of its work. I can only emphasize that without this scientific basis, we cannot ask the court to accept our *ipse dixit*, our fiat, as final; we cannot ask the court to refrain from balancing our opinions against those of others—and its own.

We have thus far seen that the police power is the basis for housing regulation and that validity will be given the administrative finding and decision of the health officer only if he acts under standards in accordance with recognized procedures. There is a good deal of talk about tightening up the procedures for enforcement. A survey was made by the Comptroller's Office in Detroit in 1945 of the feasibility of combining inspectional forces so that a building would be examined for safety of structure, electrical facilities, plumbing, and other features without duplication of visits. Similar surveys have been made

in Los Angeles County, in Newark, in Hartford. Professor Spencer Parratt of Syracuse University went on a mission last year for the National Housing Agency and the American Public Health Association and failed to find any city in which such joint and combined inspections were taking place. Frankly, he and I came to the conclusion that the cart was being put before the horse in emphasizing joint inspection (or enforcement) and that the first essential for winning court support—that presumption of validity of findings—was joint and combined establishment of regulations. Let me discuss that problem for a moment.

The development of the service state in the first half of the 20th century has seen widespread recognition in every industrialized nation of the fact that a legislature can no longer prescribe details of permitted conduct. Precisely as the setting of standards has involved research and science, the legislature has felt impelled to delegate to administrators detailed specification guided by broad statements of legislative purpose. The courts have acted as moderators in the manner that I have described to balance individual rights against the occasional overeagerness of the administrator and his scientific staff in pursuit of their objectives.

What administrators have sometimes overlooked is the opportunity afforded in the early process of making the regulations to guide, to educate, to indoctrinate, to warn, and to lay a basis for effective enforcement and ready court acceptance of the standards which lead inevitably to the desired result. The enforcement order is more apt to be given the presumptive effect that is the essence of the administrative process when properly invoked if it is based upon a carefully determined body of rules specifying the standards, the violation of which is deemed illegal. Making these rules is more than estab-

lishing a compendium of scientific data, the consensus of tried, scientific study and knowledge. It is a considered process for education, persuasion, and democratic participation. If those who are to be affected are consulted in framing the rule, they will have an understanding which is a first step toward voluntary coöperation and acceptance. The administrator will be able in this way to ascertain how far the community is ready to go with him at this time; where he will have to make his compromises. He will have a golden opportunity to explain to an intensely interested audience why he is doing what he proposes to do.

The germ theory of disease as a basis for public intervention suggests the leading rôle of the health officer in framing these regulations. But structural safety, fire prevention, the avoidance of moral hazards, the promotion of recreation and even esthetics call for the blending of social science and engineering skills. Within the past two years we have had numerous instances of the ready coöperation of health officers, housing officers, and planning officers in the use of the techniques of appraisal developed by our Subcommittee on the Hygiene of Housing. It would be a great contribution if health officers in their home communities would work quietly for the setting up of a committee within the city government on which these officers, the city engineer, and the city attorney were represented, to deal with housing regulation.

There is another reason for a broad approach that I think is important to bring out here. While I have preached objective science as the basis for enforcement, I do not want to leave the false impression that science determines all. Let me bring in boldly the word politics—and let me show that it is not necessarily frightening. Every act of the administrator—if it affects people's lives and property—necessarily

has political implications. Robert Davison, for many years director of research for the Pierce Foundation, gives a vivid illustration of the relation between science and politics in regulation. The traffic engineer will tell you that if the law limits the speed of motor vehicles to 25 miles an hour, there will be almost no traffic deaths. Yet we know that no city council will ever pass an ordinance limiting speeds to 25 miles an hour. Why? Because the councilmen know that Americans prefer *some* risk of death rather than to accept so extreme a limitation on their freedom of motion.

Similarly, a national scientific body may prescribe a test, supervise its execution, and interpret its significance to show that a given material will withstand a wind pressure of 60 miles an hour but not 80 miles an hour. It remains a *political* decision for the council or the administrative rule-makers to insist that the citizens of their town to be put to the extra expense of using materials capable of withstanding 80 mile winds in the light of climate, experience, and guesses as to the future.

Now here is the point I want to make: so long as we have one set of rules or ordinances about plumbing safety, another about structural safety, another about elevators, we make it possible for small groups with special interests to dominate the political judgments involved. It is this situation that gives rise to the stories that master plumbers and plumbers' unions collaborate in preventing the authorization of new cost-saving materials and methods. So long as the only issue for decision by the legislature is in the realm of technology of plumbing, no one else will show up at the public hearing because the larger groups cannot see how their interest is involved or what they can effectively say.

If, however, the question before the council or the rule-making body is the adoption of a housing code dealing

broadly with every phase of safety and amenity in living while encouraging the provision of economical modern homes—then you have a political issue of exciting scope. Then you may expect the consumer groups, the public interest groups, the social welfare groups—in short, the groups on whom you have to rely for backing in every advance achieved in public health work—to make themselves heard, to give the rulemakers backing for progressive steps. The arena will not be left to special interest groups by default. It will be occupied by progressive thinking people who want to enjoy more comfortable, healthful, economical living which accords with technological advance.

Housing regulation is thus seen to be an area in which an evolving scientific standard is being advanced to modify a traditional standard of property values. In setting the standard by the processes I have suggested, successful administrative regulation requires a compelling body of data to support the standard. And even more, successful enforcement requires compelling evidence that the standard has not been respected. The appraisal technique of the Subcommittee on the Hygiene of Housing should prove of great value in both these steps.

Under our democratic system, if finality is to be accorded the administrator's decision in construing the facts, the processes by which he operates must be disclosed. This is the area that the administrative lawyers have plowed most intensively. There is nothing peculiar to housing regulation that the health officer has not encountered in his attempts to regulate milk producers, bakeries, summer camps. The steps that can be taken to avoid the charge of combining prosecutor, witness, and judge have been tried out in the Department of Agriculture, and in labor boards. Health departments might experiment with using the trained hearing

officer as a sort of preliminary judge, within the framework of the department, to weigh the testimony of inspector and owner without all the formal limitations of the common-law courtroom, yet with enough record of quasi-judicial process of notice and opportunity to be heard to enable a court to refrain from substituting its judgment for that of the department. We have the record of an ordinance in Newark, N. J., providing for such machinery, but the wartime housing shortage practically compelled the city to stop substantial enforcement so that there is little experience under the ordinance.

This paper could have been devoted to a systematic exposition, in familiar administrative law terms, of the recognized steps in the quasi-judicial process. I could have used it to cover the conventional subject matter of a building code. Frankly, I thought I could help the health officer most by painting some broad background considerations to encourage him to believe that a group of men with distinctly different training and ways of looking at things has a contribution to make toward reaching goals in which he is interested. Don't be shy of them; invite them to your councils. Listen, if they talk about the experiences of a labor relations board or a grain-grading administration. Bear in mind, too, that they are talking about ideas that lie within the provinces of law and government. One of my friends wrote a book, *Administrative Regulation*; two others wrote *Regulatory Administration*. These are not plays on words alone; they recognize two faces of the same coin.

Health officers must not let themselves get into such a frame of mind that they think they have objective sciences as their discipline whereas the administrative lawyer deals in nebulous words and phrases. Building codes habitually deal in "safety factors" of four or six. These phrases are not im-

posed by lawyers and administrators. They are a short-hand way of saying that after the engineer's best calculations he is still not in a position to state with certainty what the minimum requirement shall be, so he had better increase it fourfold or sixfold.

And get together, too, with the men concerned with city planning. I recently attended a state-wide meeting of local officials in which the control of land and buildings was being discussed simultaneously in three adjacent rooms by three assemblages—building officials in one room, city attorneys in another, planning officials in a third. It is hard to recall the historic forces that have led to such complete lack of communication between technicians with large areas of common concern. Health codes, housing codes, building codes, and zoning ordinances deal with some of the same elements, for example, the quantity and shape of open spaces to be maintained on the lot. Perhaps, before we can expect united public support for our ideas, we had better get together and show the public that we have a united, coördinated set of ideas.

And even in our most 'technical moments, let us never forget that we are, in our small way, concerned with the greatest issues of human society—authority and freedom, the rights of the

group against the rights of the individual. That this issue has not been settled in two thousand years by the greatest political philosophers may cheer us a bit, but it should serve too, to keep us humble. We can hardly expect to find a permanent resolution of it in a year or two.

British Conference on Tuberculosis

The National Association for the Prevention of Tuberculosis of Great Britain announces a conference on tuberculosis in London from July 8 to 10. Although there will be special reference to the problem as affecting the British Commonwealth of Nations, the conference will deal with tuberculosis in all its aspects. Representatives from all the Dominions and Colonies have

been invited. Plans are also being made for overseas guests to see something of the anti-tuberculosis work in Great Britain. The conference is open to both doctors and laymen from all parts of the world. Particulars can be secured from the Secretary General, National Association for the Prevention of Tuberculosis, Tavistock House North, Tavistock Square, London W. C. 1.

Ideal Intake of Calories and Specific Nutrients*

FREDRICK J. STARE, M.D., F.A.P.H.A.

*Department of Nutrition, Harvard School of Public Health,
Boston, Mass.*

THE topic assigned to me is entitled: "The Problem of Working Toward an Ideal Intake of Calories and Specific Nutrients." If one thinks carefully about this topic—calories and specific nutrients—it really embraces the entire subject of nutrition. One might paraphrase the topic as follows: "The Problem of Working Toward Ideal Nutrition." As long as I do not attempt to define ideal nutrition, I shall probably steer clear of abstract arguments which will get none of us very far, unless we want to agree that an ideal intake of calories and specific nutrients, that is, ideal nutrition, is that intake which permits the development and maintenance of ideal health. I shall not attempt a definition of ideal health or a discussion of ways and means for evaluating health.

The problem of working toward an ideal intake of nutrients may be divided into three main phases:

First—evercontinuing research in nutrition to determine what is the ideal intake of calories, iron, calcium, ascorbic acid, and other nutrients throughout life so as to favor ideal health. This involves research on many fronts. Do we know all of the nutrients required by man? What are the intakes of various nutrients which best lead to improved health? How far can one carry out Dr. Sherman's concept of

"the nutritional improvability of the normal"?¹ In thinking of the ideal intake of nutrients, one must differentiate from minimum requirements. It is quite likely that minimum requirements of any nutrient for health, determined under carefully controlled conditions, are considerably less than ideal intakes under practical conditions. For example we feel that minimum protein requirements for normal adults to maintain nitrogen equilibrium and apparent good health are approximately 30 gm. per day, providing caloric intake is sufficient to maintain an ideal body weight. However, we would say that an ideal intake of protein would be nearer to the *Recommended Dietary Allowances* of 70 gm. per day. The same reasoning might apply to most any nutrient, and I think on the basis of what evidence is available today one could say that the nutrient levels 'as given in the National Research Council's *Recommended Dietary Allowances*² come as close as any information we have on ideal intakes, with the exception of calories, as I shall mention later. Just as long as one refers to the recommended allowances as allowances or ideal intakes, and not requirements, we are on safe ground, and for ideal nutrient intakes concerned with health, one should err on the side of liberality. Researches on intakes of nutrients must go hand in hand with studies on methods of measuring nutrients, studies of the function of nutrients, and evaluation of

* Presented before the Food and Nutrition Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 11, 1946.

physical and mental fitness and health.

An ideal intake of calories and specific nutrients has increased importance during growth, as has been widely practised in pediatrics for many years. Unfortunately many forget that adolescence is also a period of rapid growth. Probably less is known about the nutritional demands during adolescence than any other period of life. Likewise less emphasis is devoted to nutrition education designed for adolescents.

Of recent years the nutrient intakes during pregnancy have received increased attention and investigation. We can now better define ideal intakes for the pregnant woman as related to her health during pregnancy and postpartum and the health of her infant.

The problem of working toward an ideal intake of calories and specific nutrients must be individualized when applied to those seeking medical advice and, indeed, it takes on special emphasis under such conditions. Loss of appetite is a symptom common to most diseases, and thus intake of essential nutrients is decreased. In diseases accompanied by chronic diarrhea or poor absorption, maintenance of adequate nutrient intake is a major therapeutic problem. Convalescence, wound healing, bone growth, and blood formation all are favored by improved nutrient intake.

Occasionally one is asked: "Will we not soon know all that needs to be known about foods and nutrition and intakes for ideal health?" It is true that remarkable advances have been made in the science of nutrition in recent years, but to anyone even remotely aware of the quantitative limitations of nutritional knowledge, particularly in its application for improved health, it is far more likely to expect increasing rather than decreasing results from nutrition research.

The second major aspect of the problem of working toward an ideal intake of calories and specific nutrients is that

of nutrition education. Information from the laboratory and the clinic must be carried over to the people in such form and with sufficient emphasis that it helps mold customs on a sound nutritional basis. Information from the laboratory must be carried to those professional people dealing with health, for it will make them better able to carry out their responsibilities. Nutrition can be well and effectively taught both to the public and to professional people.

Where should one start in this problem of public education in nutrition? There are two fields that I believe are particularly promising: One, groups of children which would involve the elementary and secondary schools; and the second, the community which takes in adults as well as children. In the elementary schools, the junior and senior high schools, both public and private schools, the boy scouts, girl scouts, Junior Red Cross, and similar groups are the places where education in food and nutrition should be started and emphasized. To do this effectively requires an organized effort to introduce sound nutrition into the curricula of the elementary and secondary schools and into the curricula of the teachers' colleges. Until teachers themselves receive adequate training in basic nutrition, and in the application of this information to teaching, the inclusion of nutrition education into the daily teaching of children will be delayed.

Nutrition education is a part of health education and should be taught as such since good nutrition is essential to good health, both physical and mental. As with health education, the best results will be obtained when there is constant emphasis in *all* subject matter. Nutrition education falls naturally into the social studies and science; however, there is ample opportunity to make it function as a part of arithmetic, reading, or spelling.

Where should one start in introducing

nutrition into professional education? Again I think that best results will accrue if some instruction is included in each of the years of professional education, rather than have it all concentrated into one course. In medical education, nutrition can be well integrated with the regular medical curriculum and can be appropriately and effectively introduced during each of the four years of the standard medical course.

Nutrition education at any level is of little value if it does not carry over and result in daily use. Hence it is necessary continually to evaluate the results of nutrition, to investigate new techniques in education, and to change methods when more effective educational techniques are designed.

The third phase of the problem of working toward an ideal intake of calories and of specific nutrients is economic. Even as research yields factual information on what makes up ideal nutrition, and educational advances spread widely this information, an individual must have purchasing power to obtain the right foods, and there must be enough of the right foods properly distributed to supply all people. Attention was focused on this problem about ten years ago with the report of the Mixed Committee of the League of Nations. More recently the United Nations at the Hot Springs Food Conference and the meetings of F.A.O. have again emphasized food consumption deficiencies and food production deficiencies when considered on a world-wide basis. The Hot Springs Conference reported as follows: "There has never been enough food for the health of all people. Production of food must be greatly expanded; we now have knowledge of the means by which this can be done. It requires imagination and firm will on the part of each government and people to make use of that knowledge."

There is yet another facet of the problem of nutrition which demands atten-

tion, and which involves all three of the broad phases—research, education, and economics—that I have mentioned. That is the effect of nutrition, both good and poor, on man's social behavior. It can fairly be said that food is man's most basic environmental need. Man must eat. What man does or does not eat influences his behavior. The fundamental unity of mankind, peace in one world, no more wars—whatever expression you wish to use to describe what all of us desire but what we seem to be so muddled in trying to obtain—this spirit of good will depends on man's social behavior, which is influenced by food. Surely this problem of food, of nutrition and social behavior, is so fundamental to the concept of one world that it should receive preëminence in the plans of those who hope to bridge the chasms which exist between nations.

What do we need to be ideally nourished? What is an ideal intake of calories and specific nutrients? If we are to be strictly scientific, I do not think we know the answers to these questions—at least I do not. But we have considerable information helpful in approaching this ideal. There is probably more and better information available on an ideal intake of calories for man than for any of the specific nutrients, and yet we pay relatively little attention to this information. Generally it is not emphasized in nutrition education.

Life insurance statistics have consistently shown an increased mortality among those who are overweight. Dublin analyzed the influence of weight on the duration of life of nearly 200,000 men, and concluded that "the penalty of overweight is one-fourth to three-fourths in mortality." The increased mortality from overweight is much greater in persons beyond 35 to 40 years of age. Obesity is a dangerous condition. It increases susceptibility to diabetes mellitus, gall-bladder disease,

arteriosclerosis, gout, chronic bronchitis, pulmonary emphysema, surgical risk, and the many conditions generally classified as "degenerative diseases."

An interesting paper in the *Journal of the American Medical Association*³ this past summer reports some startling information on the prognostic significance of overweight alone, and when associated with transient hypertension and transient tachycardia. The paper presents an analysis of the medical records of nearly 23,000 army officers. The indexes chosen to demonstrate the influence of overweight on the state of health were the development of sustained hypertension and retirement or death with cardiovascular-renal diseases. Overweight alone showed significantly higher rates for later sustained hypertension than the control group, and when associated with transient hypertension and tachycardia the rate of the later development of sustained hypertension was twelve times as great as in the controls. There is no question but that overweight is dangerous to health, particularly when associated with transient hypertension and tachycardia, two conditions which are not uncommon in this country.

An interesting question that can be posed in a discussion of caloric intake is whether the treatment of obesity produces favorable results on improved health and length of life. So far as I know, this is a question that has not been given extensive study and for which there is no convincing evidence either way. Undoubtedly there are factors of degree and time involved. That is, an individual may be overweight to a certain degree and for a certain length of time and if returned to ideal weight will probably experience minimum or no impairment of health. On the other hand, a patient who has been overweight for some years, who seeks treatment because of diabetes, gall-bladder disease, or hypertension, and as part of

the treatment is reduced in weight—is that patient's health and life span improved by a lowered caloric intake? While a reduced caloric intake is part of the standard treatment in such diseases, I know of no statistical study or real evidence that any gain in health or life expectancy is obtained by it. Thus the preventive aspects of overweight may be of far greater benefit to health than the therapeutic aspects. In this regard mention should be made of reports following both world wars, of the improved general health status of individuals who were overweight and had been ill with diabetes, arteriosclerosis, and hypertension.

All obesity is nutritional. All obesity is caused by overeating, by consuming more calories than one expends. Obesity is usually classified as simple or endocrine depending upon whether it is associated with any demonstrable endocrine disorder. The latter cases are rare, generally involve an unusual distribution of the fat, and even then obesity results from consuming more calories than one expends. Why does anyone overeat? There are many reasons, and Newburgh⁴ who has made many studies of obese patients lists the following:

1. because the habit has been inculcated by the overzealous or misguided mother;
2. because great gratification is obtained from the flavors of foods;
3. because the full stomach produces a feeling of repose and comfort;
4. because some people who are struggling with difficulties which they cannot master obtain temporary respite by indulging in food;
5. because persons whose need for food is lessened by disabling illness or by the advent of an endocrine disease that lowers the metabolic rate, may not experience a shrinkage of the appetite that corresponds with the smaller need;
6. because the requirement for food is greater in youth than it is in later years, but the food habits of the earlier years may still hold sway in middle age.

It is interesting to note that the body has no adequate protective mechanism

to guard against excessive caloric intake as it does in the case of many other nutrients. The ability to absorb some nutrients, for example calcium and iron, is favorably influenced by the need for the nutrient. Water soluble nutrients, for example the water soluble vitamins, are excreted at an increased level when the need is less. Excessive protein intake results in increased nitrogen excretion. But calories from fat and carbohydrate consumed above the metabolic needs are stored.

Since overweight or obesity is definitely dangerous to health, since it is caused only by consuming more calories than one expends, since it is a condition in which prevention rather than therapy may be of greater importance to health, and since it is entirely preventable, it would appear that an intake of calories appropriate to maintain ideal weight should be given considerable emphasis in nutrition education. Seldom have I heard a nutritionist give any attention to ideal weights as part of nutrition education. I doubt if there are many nutritionists who have a very clear idea of what their own ideal body weight is. Most of nutrition education has been designed to portray the "newer knowledge of nutrition," promote a greater consumption of the "protective foods" of milk, green and yellow vegetables, citrus fruits, the "basic seven," etc., and in general has followed the slogan which I believe was coined by Dr. McCollum—"eat what you want after you have eaten what you should."

Certainly it was in the interests of improved health to encourage the consumption of foods rich in vitamins, minerals, and good quality protein, but it is likewise in the interests of improved health to drive home to people the dangers of overweight and the importance of consuming calories so as to maintain weight at approximately the ideal weight. I think the disregard of the impairment of health by consuming

too many calories has been the single big defect in nutrition education. McCollum's slogan might better be "eat to your ideal body weight after you have eaten what you should." Likewise I feel it would be an improvement in the National Research Council's *Recommended Dietary Allowances* if no figure were given for a caloric intake but rather a statement to the effect that calories should be consumed so as to approximate ideal weight. The table might well include ideal weights for men and women of average height. On an individual basis, I know of no simpler nor more important health practice for adults than to keep a written record of monthly weight. When weight starts to climb above the ideal weight, caloric intake should be promptly reduced while it still requires little reduction to bring about the desired result.

A word as to the meaning of ideal weights versus average weights is probably in order. As far as I know, the term ideal weight was coined by the Life Extension Institute and is reported by Dr. Fisk in his book *Health Building and Life Extension*.⁵ From an analysis of thousands of life insurance statistics, it was found that individuals conforming closely throughout adulthood to the average weight for any given height at age 30, have the lowest death rate. Thus average weights for men and women of specified heights at age 30 are known as ideal weight. Individuals who maintain this ideal weight throughout adulthood have the lowest death rate. Some allowance may be made for the physical type of the individual. This is generally a 10 per cent decrease for those with a slender skeletal framework and a 10 per cent increase with individuals of heavy framework. But even so, Fisk states that life insurance companies find an added death rate in any overweight group regardless of skeletal framework. Average weights are higher than ideal weights because

they are influenced by the weights of those persons who put on added weight during middle life. The term normal weight is generally used in the same meaning as ideal weight, that is, average weight for height at age 30.

For children, the ideal weights for heights and sex data widely accepted are the standards of the Child Health Association which are average figures compiled from large numbers of healthy children from birth through the age of 18 years.

Thus I feel that the problem of working toward an ideal intake of calories is important, that it is a problem nutrition education has completely ignored, and yet the solution is simple. A real effort on the part of nutritionists should be made to inform people of the dangers of overweight and to teach them that obesity is an entirely preventable disease. School physicians, home economists, and health educators should take the responsibility of teaching children in the senior high schools the penalty of overeating in adulthood. Physicians who have patients with chronic diseases that require prolonged bed rest or limited physical activity should see that

the diet is planned to avoid the insidious gain of excessive weight.

As Newburgh points out, "The chronicity of overweight and its lack of immediately disabling features and severe pain, make it easy to find excuses for delaying treatment or for being lax about it. Most people are unaware of the threat to life that excessive calorie intake involves and they can scarcely be expected to take their condition seriously until they acquire the information." Personally I feel that excessive calorie intake is the single most extensive nutritional problem affecting public health in this country. It would be largely solved if we could get the idea across to "eat to your ideal weight after you have eaten what you should."

Effect of Restricted Feeding Upon Aging and Chronic Diseases in Rats and Dogs^{*}

C. M. McCAY, PH.D.

Professor of Animal Nutrition, Cornell University, Ithaca, N. Y.

IN our modern age of nutrition the theory has been dominant that the body should be supplied with an excess of essential nutrients from the cradle to the grave. We have attempted to force the growth of animals such as chickens, swine, babies, and puppies to the maximum. We have read of balance experiments, run with inorganic elements such as calcium, in which the maximum need was indicated by the data itself. Then we have observed nutrition students increasing this level in establishing a so-called "limit of safety." We have also read experimental evidence that an animal did not store calcium in maximum capacity during growth or that a lactating animal failed to maintain a balance of calcium during the early months of lactation. Invariably, authors have concluded that such conditions were defects within the metabolism of the animal and that our goal should be to correct these defects.

On the other hand, little attention has been given to possible advantages of the ingestion of low levels of nutrients during at least certain periods of the life cycle of men and animals. Many factors have undoubtedly shaped this philosophy of nutrition. The outstanding one has probably been the short-time character of most experiments.

To date most research studies have considered only a brief fraction of the total span of life of men or animals. Except in special areas, such as that concerned with efficiency in the performance of work or in the resistance to diseases of bacterial origin, short-time studies give little evidence of possible interrelationships between the level of ingestion of nutrients and the performance of an animal or man during the whole span of life.

Inasmuch as nutrition research has made many of its advances in the course of studying farm animals, it tends to have its philosophy colored by these investigations even when the results are applied to human beings. In rearing farm animals such as swine, poultry, and beef cattle, for meat the factor of dominant importance is always the cost in terms of feed and labor to produce a pound of human food. Under most conditions the more rapidly an animal grows, the more efficiently it converts feedstuff into body tissues. Inasmuch as most meat producing animals are slaughtered before they have completed more than a third of their total span of life, little attention is paid to any factor other than a feeding program that will maintain health and efficient conversion of feedstuffs until the time of slaughter.

However, recent studies in England have devoted considerable attention to the alteration in anatomical structure of farm animals by severe restriction of

^{*} Presented before the Food and Nutrition Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 12, 1946.

essential nutrients during the growing period.¹ These afford interesting possibilities for complementary action between the inheritance of body structure and modifications during growth. In last analysis, however, the practical use of such studies depends upon the efficiency of conversion of nutrients into meat.

Human beings, however, are supposedly reared for the purpose of optimum productivity during a whole span of life.

This brief discussion of farm animals is introduced by way of contrast in order to define sharply our thinking in regard to objectives. In one case we are converting feedstuffs into meat; in the other we are attempting to produce human beings who can enjoy optimum health and hence perform a maximum of useful work during the whole span of life.

In order further to clarify our philosophy, brief consideration should be given to our major objective in research in the field of aging or gerontology. The opinion is rather general that researchers are attempting to drag out the period of decrepit old age with its resulting vast economic burden due to illness and dependence. Quite the opposite is the case, since the objective of research upon aging is the discovery of ways of maintaining optimum health during the declining years of the life span so that this burden due to dependence will be alleviated.

From this introduction it might seem that applied agriculture has little interest in research in gerontology other than that the farm population must bear its share of the burden of the aged who become ill so they cannot carry their portion of farm labor. This is not entirely true since it is economically important for certain classes of livestock to have a long adult life. In different parts of New York State the average dairy cow has a productive life of only

5 to 7 years. However, the potential productive life of the cow is about 20 years. In this case a long productive life is economical. In fact, one group of Jersey and Guernsey breeders have favored a restricted diet during growth for these two breeds of cows in order to produce the best types and the most productive animals. Like the Shetland pony, these breeds originated on islands where the limited supply of food retarded the growth and restricted the ultimate body size.

LOW ENERGY DIETS

For centuries there are records of individuals, religious sects, and geographical areas in which people from choice or necessity passed much of their lives upon diets that barely prevented starvation. One of the greatest advocates of such nutrition was Luigi Cornaro (1464-1566). His book passed through a number of editions and was published in America in 1917 under the title of *Art of Long Living*. He advocated a very simple diet of about 14 ounces of food per day. This consisted of soup, bread, and an egg each day, with a small addition of meat for those who could afford it. Of course, Cornaro drank wine instead of water with his simple diet.

One can find other records of such human diets. However, we can draw few satisfactory conclusions about results because we know too little about the quality of the food and the many other variables that influenced the lives of these men. From the viewpoint of modern nutrition it seems difficult to understand how men like Cornaro survived. It is equally difficult to understand how the poor of many lands have lived for centuries upon simple diets. When we add together the twenty-five to fifty vitamins, fatty acids, inorganic elements, and amino acids that are recognized today as essential constituents of human food, it is almost

unbelievable that survival was possible, especially after men started to process and destroy natural foods.

This complex problem of providing a diet in minimum amounts that will provide optimum levels of all essential nutrients has been stressed because it is a matter of supreme importance to basic research in animal experiments. Until modern times the effects from both human experience during periods of famine, and of animal experiments in the laboratory in feeding low energy diets, were confused because such diets under both conditions were usually deficient, not only in calories but in numerous other essentials such as proteins, calcium, and vitamins.

Before proceeding with a brief discussion of controlled experiments with animals, it may be well to review one of the outstanding records of human experience, namely the studies of Chadwick.² Edwin Chadwick (1800–1890) is best known as a lawyer-sanitarian who pioneered in England a century ago in the improvement of sanitation, housing, education, and factory labor conditions. Even today most of us can well afford to have constantly before us for rereading, the great works of Chadwick edited by B. W. Richardson under the title of the *Health of Nations*.

Chadwick's contributions to our knowledge of low energy diets resulted from a comparative survey of prison diets used in England. His study was made in coöperation with the statistician William Farr in the years 1830–1832.

Due to the diversity in food allowed in the 128 prisons under study it was found that these prisons could be divided into three classes. In one only 128 ounces of solid food were allowed per week, in the intermediate class the allowance was 213 ounces, and in the highest 218. These two latter were close together on amounts but differed considerably in the money expended.

At this period in England, agricultural laborers consumed only 122 ounces of food weekly. Unfortunately we cannot calculate these diets into modern terms of proteins, fats, etc.

The outstanding results of this study were the much lower death rates in the prisons using the lowest food allowances in comparison with the other two. Chadwick concluded, "The average excess of sickness which was the concomitant of the excessive forms of dietary, amounted to no fewer than five thousand-eight hundred and eighty-two cases per annum, yielding an unnecessary mortality of ninety-four." Although there is no mistaking the conclusions of Chadwick it is difficult to fit them to the meager data upon illness cited by Richardson. If the original data were available it would be interesting to repeat the calculations using modern methods.

Inasmuch as we have reviewed the literature elsewhere in the limited field of animal research dealing with the interrelationships between restricted diets, growth rate, and the diseases of old age, we will only consider a few earlier works at this time.³ Jackson has provided thorough reviews upon the general subject of inanition.⁴

One of the earlier studies, that have been forgotten in modern times is that of Moreschi.⁵ He extended earlier British observations indicating that restriction of foods slowed or prevented the growth of tumors in animals. In his studies with mice Moreschi transplanted tumors and followed their rate of growth. He found the tumor grew in relation to the amount of food allowed the animal. Mice fed on restricted diets lived longer. Under some conditions of restricted diet he found it difficult to transplant tumors.

These original findings of Moreschi which have been rediscovered in modern times were probably neglected because Rous made a similar study with rats⁶

and failed to get any effect from restriction of the diet. In the report of Rous, there is no evidence, however, that the results of Moreschi with mice were in question.

In addition to interest in diseases in the study of restricted diets, another outstanding problem concerns the ability of an immature animal to resume growth after long periods of retardation. For nearly twenty years we have given attention to this problem, using several species, namely, the dog, the rat, and the brook trout.

Although the use of restricted diets offers vast opportunities in the modification of types within breeds of dogs, little attention has been given to this subject. In 1911, Aron⁷ reported a few studies with mongrel puppies in which he retarded the growth by the restriction of food. Under such conditions he found that the skeleton continued its growth to a limited extent. After a puppy was restricted for 350 days it seemed to have lost its ability to resume growth and attain a normal size.

In two preliminary studies using dogs of known breeds we have extended this work.^{8,9} In the first, a litter of five Saluki pups was used. Three of these were allowed to grow normally and two were retarded until 440 days of age with the restricted diet starting when the pups were 3 months old. The growth of the tibia in each pup was followed by means of x-ray photographs made at regular intervals. There was slow growth of the bones during the first 300 days of the study. After re-alimentation there was no evidence that the retarded pups could attain the size of the control animals.

Dr. W. T. James made a number of studies upon these dogs to determine if there were differences in rate of learning. He found none. He did find a lower heart and breathing rate in the retarded dogs. When required to perform a given amount of work such as

walking there was obviously a greater strain on the body of the underfed. Housed in a warm kennel, but provided with an outdoor run, these Salukis, which are naturally as thin as greyhounds and have limited hair protection, survived a cold winter.

A second experiment was completed just prior to the war using three long haired terrier puppies from a Scotch-Cairn cross. Two of these were females and one was a male. When 65 days old the male and one female puppy were started upon a restricted diet designed to provide an adequate intake of all essential nutrients except energy, even when fed at maintenance levels. The other female puppy was given all the food desired.

All puppies weighed 4 pounds at the start of the study. At the age of 357 days the two retarded animals weighed slightly more than 9 pounds each, while the control weighed 15. Re-alimentation started at that time. At the conclusion of the study when the pups were 374 days old, the control female and the retarded male weighed 15 pounds while the retarded female weighed 13.5 pounds. Careful measurement of the leg and head bones indicated that the size of the skeleton was proportional to the body weight.

Both of these preliminary studies with dogs confirm the findings of Aron that if dogs are maintained upon restricted diets so that growth is retarded for a period of a year, the animal loses its power to attain full adult size. In the second study the pups were kept in unheated kennels and had no difficulty in surviving a cold winter. The retarded pups were exceptionally active and alert. Contrary to normal dogs they were so hungry that they would eat dog meat if offered them. Thus hunger drove them to cannibalism.

STUDIES WITH WHITE RATS

Some of the finest papers of the late

Professor L. B. Mendel were concerned with the problem of the suppression of growth and the capacity to grow.¹⁰ He was able to retard the growth of rats for more than a year. In one case he kept a rat on a restricted diet for 532 days and found it still retained the capacity to grow. Since Mendel's work in 1914, advances in our knowledge of nutrition have permitted the design of superior diets. Today we can feed mixtures enriched in essential nutrients so that we are more certain of providing for needs of the body if we wish to restrict the growth by limiting the energy intake.

Of course we can never be sure of the ultimate limiting factor under such conditions. When calories are severely restricted, the body may utilize essential amino acids or even vitamins for fuel. Hence these may be the ultimate units that prevent normal growth.

Since 1930 our studies upon aging in rats have been of three types: In the first we have retarded rats for long periods and determined the effects in terms of diseases that developed and the total span of life.¹¹ In the second we have introduced dietary variables in the middle of the life span when rats were about a year old.¹² In the third, various attempts have been made to improve normal human diets by the addition of natural foods.¹³

Three long series of these restricted diet studies have been completed since 1930. All have given similar results. Rats long retarded by diets with excess of recognized essential nutrients, but inadequate in energy allowance to permit growth, far exceed the normal span of life for their species. The oldest rat thus far lived 1,456 days, while the normal span of life for a white rat is about two years.

The growth impulse of rats maintained upon restricted diets for long periods persists strongly for 900 days. After this it tends to decline and is lost

in various individuals. In one case it persisted in a rat for 1,150 days. When such rats are re-alimented and resume growth even after 900 days they always fall short of attaining the adult size that would have been achieved if they had grown normally from an early age. Thus, in one series of studies the length of the tibia varied from 3.8 to 4.1 cm. for normal adult males, while the mean lengths for those retarded 300 and 900 days respectively were 3.7 and 3.5 cm.

Of all the organs and tissues of the body the bones seem the most persistent in maintaining their growth. Likewise, in retarded animals the bones seem to persist in the deterioration of old age through the loss of inorganic materials. Thus they become thin and fragile or we may say "old" in rats prevented from attaining adult size beyond their normal span of life. At the same time these bones are aging, other parts of the body such as the hair maintain their youthful character.

From our earliest studies it was evident that the retardation of growth upon diets of excellent quality, but restricted in amount, resulted in a long span of life because the retarded rat was less subject to the usual terminal diseases that start in the second year. Thus in the first series of studies made in the early '30's no tumors were observed among retarded rats until after they were allowed to grow. On the other hand, about 12 per cent of the rats allowed to develop normally had tumors. However, the organ that seems to fail first in rats is the lung. Second to this organ are probably the kidneys. In old age the rat seems to have little trouble with the heart and blood vessels.

In the first two series of retarded growth studies only limited attention was paid to pathology. In the course of this research it became evident that teamwork between nutrition and pathology afforded the most effective method devised thus far for attacking the

problem of chronic diseases of old age.

The third large study started in 1939 and involved 500 rats. Some of these were killed at regular intervals, in order to follow the development of chronic diseases. Dr. John A. Saxton, Jr., has published a number of summaries of observations upon these rats.¹⁴ He has found that the chronic pneumonia which seems to terminate the lives of most old rats, develops much more slowly in those fed restricted diets and thus retarded in growth. The elasticity of the lung tissue seems to be better maintained in these underfed animals.

In order to penetrate still further behind the pathological picture, Dr. O. H. Lowry and associates¹⁵ have attempted to apply histochemical methods to the study of the tissues of some of these rats. They found the kidney tissues afforded most evidence of changes with age. They believed the restriction in calories may have favored this organ in keeping it younger in retarded animals. Inasmuch as the daily ingestion of proteins, vitamins, and inorganic constituents was kept the same for all rats, the aging of or injury to the kidneys in normal rats could not be referred to any of the classical reasons such as a difference in the amount of nitrogen excreted daily. This burden was the same for all animals. Hence the kidney changes must have been associated with aging. However, in this case the retarded animals seemed to have maintained "younger" kidneys just as they did more elastic lungs.

The restriction of calories during the latter half of life is also effective in extending the total span of life of the rat just as it is in the case of man.¹² However, this extension is small compared to that resulting from severe limitation of calories during the growing period.

Little research has been directed toward either restriction of special nutrients or the effect of specific excesses

upon the diseases of old age. Kon has indicated that the absorption of calcium declines in old age,¹⁶ so that the allowance should probably be increased. However, Shields and Mitchell¹⁷ have found no evidence that higher levels of calcium in the diet extend the span of life of rats. It is probable that Kon was concerned with a border-line allowance of this element while Mitchell's lowest level made adequate provision for the needs in old age even with a decreased absorption rate.

In our own laboratories we have had experiments in progress during the past few years¹¹ in an attempt to answer three questions:

1. Will a moderate consumption of coffee equal to a cup per day for man modify the life span?
2. Can the typical diet consumed in the northeastern part of the United States be improved by supplementation with vitamin concentrates?
3. Can this diet be improved by changes suggested by modern nutrition such as the use of more organ meats, whole wheat bread, and milk?

These experiments have been described in detail elsewhere,¹¹ but the results can be expressed here in a few words. As far as the life span of the white rat can serve as a criterion, there is no evidence of improvement in this average human diet either by supplements of vitamins or by increases in such foods as liver, milk, and whole wheat bread. Furthermore, there is no evidence of modification of the life span from the daily ingestion of a moderate amount of coffee beverage. In fact, two groups of rats indicated significantly favorable responses to this beverage.

Following this study, small groups of rats were forced to consume no other beverage than coffee from the time of weaning. This study now has reached its third generation. In other words, two generations of rats have grown to maturity, reproduced and reared young,

with coffee to drink instead of water. The growth rates of the rats were slightly slower, but they attained the same adult size and seemed to have no trouble in reproduction. This study has not been extended to a consideration of the life span.

At present we are starting a new series of experiments to determine whether the daily ingestion of large amounts of fluid will tend to preserve the kidney against age changes in the rat. One of the variables in this study will be coffee. Another will be liquid milk. A technique has been devised by which the rat can be induced to consume three to five times as much water as it drinks normally. This technique is the same as that used previously in studying the effect of acid beverages upon teeth.¹⁸ It makes use of the fact that a rat will drink much more of a solution containing 10 per cent sucrose than it will of water. The outcome will be known about four years from now.

SUMMARY

The purpose of all research upon aging is to find means of alleviating the chronic diseases of old age. Thus we can look forward to more productive years and less financial dependence in man. Severe restriction in food intake has long been advocated by individuals and certain sects. It has been essential in many nations. Until modern times, however, such restriction has had attendant risks since we were unfamiliar with numerous essentials that must be included in diets.

Studies with dogs and rats covering the past sixteen years have been reviewed. Puppies can be severely retarded in growth by restriction of food. They seem to suffer no ill effects in the course of a year even when kept in cold kennels during the winter. However, such puppies do not attain normal body size even when the restriction is maintained for only a year.

Three long-time experiments in maintaining rats during the growing period upon diets adequate in known essentials except calories indicate that the life span is much extended. This is due in part to the slower development of chronic diseases of the lungs in rats whose growth is retarded by diets low in energy value. Such diets and such slow growth also lead to a much lower incidence of tumors and possibly to less aging of special organs such as the kidneys and lungs.

Under conditions of restricted diets, bones seem to be the most persistent in their growth. However, rats, like puppies, retarded for even 300 days cannot attain normal adult size. However, rats seem to have more ability than other species to resume growth after long periods of suppression.

A few recent studies indicate that excess of special food substances does not succeed in extending the life span of rats by supplementing a normal human diet with either vitamins or by means considered especially worth while, such as additions of liver, whole wheat bread, and more milk. The ingestion of moderate amounts of coffee as a beverage had no unfavorable effect upon the life span of rats. New studies are under way in which the amount of liquid ingested daily is the principle variable.

Apprenticeship Training in Public Health Nursing

The Division of Public Health Nursing of the New York State Health Department announces a plan for an apprenticeship in public health nursing. It is designed primarily for the young graduate nurse who wishes to try herself out in public health nursing before she decides upon a career. A period of field training service of from 4 to 12 months in a local health district will be provided at a recommended minimum salary of \$1,800, but depending on local salary standards. Upon successful

completion of an apprenticeship, the candidate is eligible to apply to the State Department of Health for a training fellowship in public health nursing at an approved university program of study in public health nursing. This training in turn meets civil service requirements for appointment as a public health nurse for field service.

Effect of Ultra-violet Irradiation of Classrooms on Spread of Measles in Large Rural Central Schools*

Preliminary Report

JAMES E. PERKINS, M.D., F.A.P.H.A.,
ANNE M. BAHLKE, M.D., AND HILDA FREEMAN SILVERMAN

New York State Department of Health, Albany, N. Y.

STUDIES made in the past nine years by William Firth Wells and Mildred Weeks Wells¹⁻⁴ in Philadelphia and its suburbs on the effect of ultra-violet irradiation of classrooms on the spread of measles, chickenpox, and mumps in school children, have suggested that such irradiation has reduced the spread of these diseases, particularly measles, in the classrooms studied. In an attempt to repeat their observations, similar experiments have been undertaken by the New York State Department of Health† in three rural centralized schools in upstate New York.

Actual observations in these experiments did not begin until January, 1945, but the extensive measles epidemic which occurred in New York State in the winter of 1945-1946 makes this early preliminary epidemiological report possible.

The decision to conduct the study in centralized rural schools was determined primarily by their having certain characteristics which constitute highly de-

sirable experimental conditions. Obviously, a decisive demonstration would be most likely if the children under study associated with other children to only a very limited extent outside the environment under observation, in this instance the school environment. Such a situation is approximated in the rural school. In contrast to the experience of the city child, rural children enrolled in a centralized school have most of their contact with one another within the school environment, either in the school building or on the school bus.

Three schools were placed under observation: the Cato-Meridian, Port Byron, and Mexico Central Schools. The State Education Department prepared a list of a number of such schools in accordance with criteria established by us, and these three were chosen from that list because of their similarity and relative proximity to one another. All three were constructed within the past 10 years on the same general architectural plan and have essentially the same ventilating systems (central fans, zoned, capable of delivering 30 cu. ft. of air per minute per child). The floors throughout all three schools are waxed as needed with a commercial floor wax and all three are swept with mops treated with an oily, anti-dust preparation. All three supervising principals

* Presented before the Epidemiology Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 14, 1946.

† This study has been made by a team of the department, with the various aspects represented as follows: epidemiological, Drs. Perkins and Bahlke; statistical, Hilda F. Silverman; engineering, C. R. Cox; and bacteriological, F. W. Gilcreas, assisted by Hazel V. Roberts.

and their boards were sympathetic with the experiment and were willing to give full coöperation. Each of the three schools has a full-time nurse and an adequate system of keeping health records. The pupil populations are comparable socially and economically, and each school has an enrollment of over 600 pupils: 620 in Cato-Meridian, 850 in Port Byron, and 900 in Mexico.

The Cato-Meridian and Port Byron schools are in Cayuga County, and the Mexico school is in adjacent Oswego County. The Cato-Meridian school is situated in a field half way between the villages of Cato and Meridian, which are two miles apart. Cato has a population of approximately 400, and Meridian 300. All the pupils in this school are transported in school buses. The Port Byron school is located in the village of Port Byron, which has about 950 inhabitants, and 80 per cent of the pupils ride to school in buses. The Mexico school is in the village of Mexico where the population numbers 1,350, and 70 per cent of these pupils ride the buses.

The Cato-Meridian school has been fully equipped throughout with ultra-violet lamps except for the gymnasium where there are technical obstacles to such installations. All three schools have at least two sections of each grade, and in Port Byron the room housing one section of each grade through the 8th is irradiated, whereas the room with the other section of each of these grades has no ultra-violet lamps, and thus serves as a control. All places of common congregation within the school (again except for the gymnasium) are irradiated. The Mexico school, with no ultra-violet lamps, serves as a wholly unirradiated control school.

Dr. L. J. Buttolph of the General Electric Company has acted as the consultant lighting engineer in the study. He determined the nature of the original installations and has supervised their

maintenance. Irradiation throughout is by the indirect method with the shielded fixtures suspended about 7 ft. from the floor. The fixtures are of the wall-attached, trough-like type, equipped with an "Alzak" finished aluminum reflector in the shape of a cylindrical parabola. Each fixture is equipped with a 30 watt low pressure mercury vapor germicidal lamp. The total number of fixtures per room varies from one in a few very small rooms to eight in the auditoria and cafeterias. The average classroom has three fixtures, one each on the front and rear walls, and one on the side wall opposite the windows. The hall fixtures are of a double trough type containing two 15 watt tubes per fixture, and are hung from the ceiling in the center of the corridor.

Measurements have been made regularly throughout the study of the radiation output from the lamps in both schools to assure their maintenance at proper operating levels. In general an attempt has been made to maintain an average ultra-violet light intensity of 10-20 milliwatts per sq. ft. throughout the upper air; and 0.2 to 0.5 milliwatts per sq. ft. (or microwatts per sq. cm.) at face level of standing pupils.

It should be noted that despite such vigilance several cases of conjunctivitis, erythema, and desquamation were encountered among the teachers of both schools. So far as could be determined, no pupils were affected. Since most of the faculty stand while teaching, this selectivity can be explained on the basis of a difference of facial levels in the two groups. The symptoms occurred for the most part in fair complexioned individuals and were due to stray radiation from imperfect fixtures or indirect radiation reflected from the highly reflective unpainted plaster ceilings. In every instance the situation was corrected either by applying adhesive tape to a portion of the reflectors or by disconnecting a lamp in the room. Such

measures did not cut the irradiation in the room below what were considered to be adequate levels.

Local arrangements were made with school personnel for periodic checking for burned out tubes, and weekly dusting of the tubes with a clean dry cloth.

Evaluation of results is an involved problem by virtue of the complexities of the environment in which the study is being performed. Such evaluation has been made from analysis of data obtained through several basic procedures which may be outlined briefly as follows:

All absences due to illness in each of the three schools are investigated by the school nurse. Upon notification of a communicable disease in the school population, confirmation of the diagnosis is obtained from the private physician, school physician, or other reliable observer. For the purposes of the present study, the establishment of a diagnosis of measles is followed by an attempt to determine the exact date of onset. The period of infectiousness has been arbitrarily considered to extend from 48 hours before the initial symptoms to 9 days afterward, which in the average case means 5 days before onset of the rash and 5 days afterward. On the basis of these limits it is ascertained which children in the classroom and on the school bus were exposed to the primary case. For the determination of secondary cases the incubation period (that is, from exposure to onset of symptoms) has been arbitrarily set from 7 to 15 days.

In each case an earnest effort is made to determine the source of infection, whether it be in the classroom, on the bus, in the home environment, or elsewhere. In the last circumstance, however, only readily detectable sources are explored, such as extra-school playmates, Sunday school classes, and children's parties.

These historical and epidemiological details are recorded on four separate

forms. Each bus driver maintains a daily record, similar to the teacher's class register, which notes which children rode each of the two daily trips. The school nurse fills out a detailed individual history form for each case with information as to onset of symptoms, clinical characteristics, and contacts. The field epidemiologist and statistician, working with the above information and the class registers, draw up continuous daily records of attendance for each class and each bus from 48 hours prior to the onset of the first case in the specific class or bus to 15 days after the last known infection within the group.

In addition, detailed daily records are kept by the school custodians as to the operation of the ventilating systems, indoor and outdoor temperature variations, relative humidity, and similar information. Furthermore, regular monthly air samples have been obtained for bacteriological analysis from representative classrooms in all three schools, employing both the open plate method and the Wells air centrifuge. These bacteriological data, however, will not be covered in this report.

RESULTS

Overall Morbidity

Since nothing was done to control the spread of infection in the school buses and since there seemed every reason to believe that school buses are as important environments for the spread of measles as classrooms, if not more so, it was not anticipated that there would be any overall reduction in morbidity. If the ultra-violet lamps proved to be of any value in reducing the spread of the infection within the classroom it was felt this would be manifested by changes in the pattern of the cases on a chronological basis rather than in variations in the percentage of susceptible children ultimately developing measles in the irradiated classrooms as compared

TABLE 1
Per cent of Total Cases Occurring in the First Six Grades

School	Enrollment *		Number of Cases		Per cent of Cases
	Total	Kindergarten through Grade 6	Total	Kindergarten through Grade 6	Kindergarten through Grade 6

Mexico	904	492	146	134	91.8
Total	2,368	1,389	510	475	93.1

* Exclusive of children enrolled for less than 30 days.

with the non-irradiated classrooms.

In the course of the outbreak 510 cases occurred among the 2,368 pupils enrolled in the three schools (Table 1). Of the 510 cases, 475, or 93 per cent, occurred among children in the kindergarten and first six grades. Subsequent analyses will be confined to these grades, as the number of cases occurring in each of the higher grades is too small to give statistically significant figures. The analyses are limited to the lower grades also because histories as to a prior attack of measles were less accurate in the upper grades, and because ultraviolet lights were installed only through the 8th grade in the Port Byron school. This limitation was dictated by the fact that beyond the 8th grade the pupils do not remain in one room throughout the school day but circulate from one room to another according to the subject they pursue at a given class hour.

Before considering attack rates, it is

of interest to compare the variation in susceptibility by grade in the three schools, as determined by a history of no prior attack of measles. Table 2 shows that the three schools were roughly comparable as to susceptibility to measles at the start of the epidemic, although Mexico quite consistently had somewhat lower percentages of susceptible children at the various grades.

In Table 3 the percentage of the susceptible children who developed measles is indicated for each grade in each school. It will be noted that there is no consistent difference between the three schools, with 78 per cent, 84 per cent, and 69 per cent, respectively, of the children in these grades of the Cato-Meridian, Port Byron, and Mexico schools developing the disease.

This lack of significant variation in total attack rates in the irradiated and non-irradiated classrooms may be indicated further by splitting the Port

TABLE 2

Byron grades into irradiated and non-irradiated sections (Table 4). Because of the small numbers, rather marked fluctuations in percentages occur but it is evident that there is no significant difference in the attack rate among susceptible children in the irradiated rooms compared with those non-irradiated. Combining the first six grades for each section 82 per cent of the susceptibles in the unirradiated sections acquired measles compared with 86 per cent of those in the irradiated sections.

At this point one might consider the desirability of a more refined analysis in the calculation of measles attack rates, taking into consideration not only the susceptible children in individual classrooms but the volume of air and

the air change. Such a complex analysis is hardly indicated, however, in view of the apparent uniformity of ventilation in the various classrooms, the essential uniformity in the number of susceptibles per room for a given grade, and the uniform size of the classrooms. Of the 43 rooms represented in the first six grades of the three schools, the range in cubic content varies from only 7,400 to 8,700 cu. ft. in 40 of them. Twenty-five of these 40 rooms, in fact, are exactly the same size (8,448 cu. ft.). The remaining three rooms are of the following capacity: 6,870 cu. ft. (Kindergarten B in Mexico); 11,352 cu. ft. (Kindergarten A in Port Byron); 11,880 cu. ft. (Kindergarten B in Cato-Meridian).

CHART 1

Chronological Pattern

When one looks at the pattern formed in each school by cases by date of onset a definite difference is noted in the three patterns, as shown in Chart 1. From this chart it is immediately evident that the Cato-Meridian school experienced an extended outbreak with cases dribbling along from December 31, 1945, to April 17, 1946. In contrast, the Mexico school experienced a sharply explosive outbreak about the first of February. Between these two patterns lies the pattern for Port Byron with an outbreak less explosive than that in Mexico but not so protracted as that experienced in Cato-Meridian.

These variations in pattern correspond to the relative degree of irradiation of the three schools, since Cato-Meridian school was completely equipped with lights, Mexico school had none, and in the Port Byron school half of the sections of the lower eight grades were irradiated while the corresponding halves of the same grades were not.

In an attempt to determine whether these variations in pattern are actually

due to the ultra-violet lights a number of analyses were made. If one separates the cases in the Port Byron school according to whether they occurred among children in irradiated or non-irradiated classrooms, another distinct difference in patterns results, as shown in Chart 2. It is evident from this chart that the cases occurring in classes with ultra-violet lights were spread out over a longer period of time than the cases which occurred in the classrooms without ultra-violet lights. Since these classes otherwise apparently were comparable, it is difficult to ascribe these differences in pattern to anything other than to the presence or absence of the lights.

The variations in explosiveness of cases in the irradiated classrooms versus non-irradiated classrooms may be measured by calculating the interval in days covered by the dates of onset for the middle 80 per cent of the total number of cases; that is, 40 per cent of the cases above and 40 per cent below the median case. For the combined grades, the intervals for the unirradiated

CHART 2

classrooms in the Mexico and Port Byron schools were 15 and 17 days respectively, and for the irradiated classrooms in Port Byron and Cato-Meridian schools, the intervals were 24 and 26 days, respectively.

Returning to a consideration of the contrast between the protracted smoul-

CHART 3

dering outbreak in the Cato-Meridian school and the patterns for the Mexico and Port Byron schools, it would be pertinent to determine what variation in pattern occurred in these three schools in the last previous outbreak of measles in each. Unfortunately, the school health records are such that it is impossible to settle this point from them. However, it is possible to estimate the picture from reports received in the State Department of Health of cases in the 5 to 14 year age group for the townships served by these school districts for the year in which the last previous measles epidemic occurred (1941 for Cato-Meridian and Port Byron school districts, and 1942-1943 for the Mexico school district).

Such cases of measles reported by months in these years would necessarily seem to reflect the pattern in the schools themselves. The patterns of total cases are indicated in Chart 3. From the per cent of total cases reported in each month it will be noted that the outbreaks were very explosive in all three school districts, in marked contrast with the variations in patterns for the three schools in 1946.

School Rooms Versus Buses in the Spread of Measles

It may be assumed that the differences in the chronological pattern of measles incidence in the three experimental schools were due, in part at least, to the presence or absence of ultra-violet irradiation in the classrooms of those schools. If the school buses were an important factor in the spread

of the disease and contributed significantly to the equalization of the total attack rates, the data should show this.

Any attempt to analyze the data in relation to bus operation is made difficult through numerous uncontrollable factors. The most obvious of these, the fact that practices with regard to bus operation vary markedly from school to school, makes comparisons between the three schools hazardous, and doubtless other variables are equally important. However, all such factors would seem to be unimportant as they relate to the children in one particular school. Thus it is possible to make what should be valid comparisons between attack rates in children in irradiated and unirradiated classrooms of the Port Byron school according to whether they did or did not ride buses. These rates for the kindergarten and first six grades are presented in Table 5.

It will be noted that the attack rates among the bus-riding and non-bus-riding susceptibles in unirradiated classrooms was essentially the same, 83 per cent and 77 per cent respectively. In contrast to this the attack rate of 90 per cent in bus-riding susceptibles of the same grades in irradiated classrooms is significantly greater than that of 69 per cent among the irradiated non-bus riders. The school bus, therefore, did appear to play a somewhat greater role in the dissemination of measles among children in irradiated classrooms than among those not irradiated.

The relatively high attack rate of 69 per cent among non-bus riders attending irradiated classrooms is interesting,

TABLE 5

Measles Attack Rates among Bus Riders and Non-bus Riders of Port Byron School Kindergarten through Sixth Grades

	Unirradiated Classrooms			Irradiated Classrooms		
	Susceptibles	Cases	Attack Rate per 100	Susceptibles	Cases	Attack Rate per 100
Bus riders	83	73	83.0	101	94	90.4
Non-bus riders	31	24	77.4	26	18	69.2

but not surprising when note is made of the fact that these were children living in the village. Presumably they had greater opportunity for extra-school contact with other children than bus riders who live for the most part on outlying farms, and this extra-school contact could have been an important contributory factor to the incidence in this non-riding irradiated group.

CONCLUSIONS

These analyses of the occurrence of measles in three centralized rural schools seem to indicate that ultra-violet lights in the classrooms did modify the spread of measles in those classrooms. It is not to be construed, however, that upon the basis of these findings, the authors are recommending routine installation of ultra-violet lamps in classrooms.

Further experimental investigation is needed, and the department intends to

continue its studies, observing the effects on other communicable diseases, particularly chickenpox and mumps. In accordance with original plans, the study is to be modified by the installation of triethylene glycol vaporizers in the school buses.

ACKNOWLEDGMENTS—The excellent coöperation of the entire school personnel of all three schools and the facilities of the Syracuse Department of Health Bureau of Laboratories under the direction of Dr. O. D. Chapman are gratefully acknowledged.

Purchase of Federal Surplus Property

The National Institute of Governmental Purchasing (730 Jackson Place, N.W., Washington, D. C.) calls attention to the abandonment of priorities in purchasing federal surplus property that is threatened by the recent decontrol of prices. It has sent an official statement of policy to every member of Congress and other public officials and businessmen in which it deplores the

hardships already put in the way of state and local governments in their attempts to buy surplus properties. Price decontrols increase these hardships. The statement calls upon the Surplus Property Administrator to appoint an advisory committee of state and local purchasing officials to plan a constructive program for making surplus available to tax supported agencies.

Use of Census Tracts in the Analysis of City Health Problems*

HOWARD WHIPPLE GREEN, F.A.P.H.A.

Secretary, Cleveland Health Council, Cleveland, Ohio

ALL cities of 250,000 inhabitants or more at the time of the 1940 Census except San Antonio, Tex., and 24 cities with fewer than 250,000 population were laid out in census tracts prior to the 1940 Census.

The Bureau of the Census, following the 1940 Census, published a series of bulletins entitled "Population and Housing: Statistics for Census Tracts," one for each of the 60 census tract cities. With such basic data the tabulation of births, deaths, and cases of reportable diseases by census tract of residence, takes on special significance.

It is common procedure to analyze deaths by age, sex, and cause of death by states. It is also common procedure to calculate infant mortality rates and death rates by counties and large cities within a state, but only recently have infant mortality rates and death rates by cause been analyzed for small sections within large cities. And even more recently have studies been made of the variations by economic tenths within large communities.

The Cleveland five-city area—Cleveland, Lakewood, Cleveland Heights, East Cleveland, and Shaker Heights—has, for statistical purposes, been broken down into 10 economic tenths. The 257 census tracts have been arranged in array by rent of tenant-occupied

homes and rent equivalent of owner-occupied homes. Sufficient census tracts have been accumulated from the lower end of the array to make up one-tenth of all families. This area is called the lowest economic tenth. The process is repeated to obtain the second, and so forth. Those remaining make up the highest economic tenth.

The map shows the census tracts included in each of the 10 economic tenths of the Cleveland five-city area. There are somewhat more than 29,000 families with 100,000 men, women, and children in each economic tenth.

The possession of radios in 1930, automobiles and mechanical refrigeration in 1934, telephones in 1937, radios, mechanical refrigeration, tubs or shower baths, and central heating in 1940 varies by economic tenths. The 1940 level of education also varies by these economic tenths.

More than half, 53 per cent, of the families in the Cleveland five-city area had radios in April, 1930. The percentage of families with radios varied from 23 per cent of those in the lowest economic tenth to 80 per cent of those in the highest economic tenth.

While the same percentage of the families in the Cleveland five-city area had automobiles in January, 1934, the percentage varied from 24 per cent of those in the lowest economic tenth to 86 per cent of those in the highest.

Nearly a fifth, 19 per cent, of the families in the Cleveland five-city area

had mechanical refrigeration in January, 1934, 1 per cent of the families in the lowest economic tenth and 61 per cent of those in the highest economic tenth.

While 38 per cent of the families in the Cleveland five-city area had telephones in May, 1937, 8 per cent of those in the lowest economic tenth had telephones and 88 per cent of those in the highest economic tenth.

Table 1 shows the figures for each economic tenth.

Ninety-six per cent of the families in the Cleveland five-city area had radios in April, 1940, 87 per cent of those in the lowest economic tenth and 99 per cent in the highest economic tenth.

Fifty-six per cent of the families in the Cleveland five-city area had me-

chanical refrigeration in April, 1940, 18 per cent of those in the lowest economic tenth and 91 per cent of those in the highest economic tenth.

Ninety-two per cent of the families in the Cleveland five-city area had tubs and shower baths in April, 1940, 68 per cent of those in the lowest economic tenth and 100 per cent of those in the highest economic tenth.

Seventy-eight per cent of the families in the Cleveland five-city area had central heating in April, 1940, 22 per cent of those in the lowest economic tenth and 99 per cent of those in the highest economic tenth.

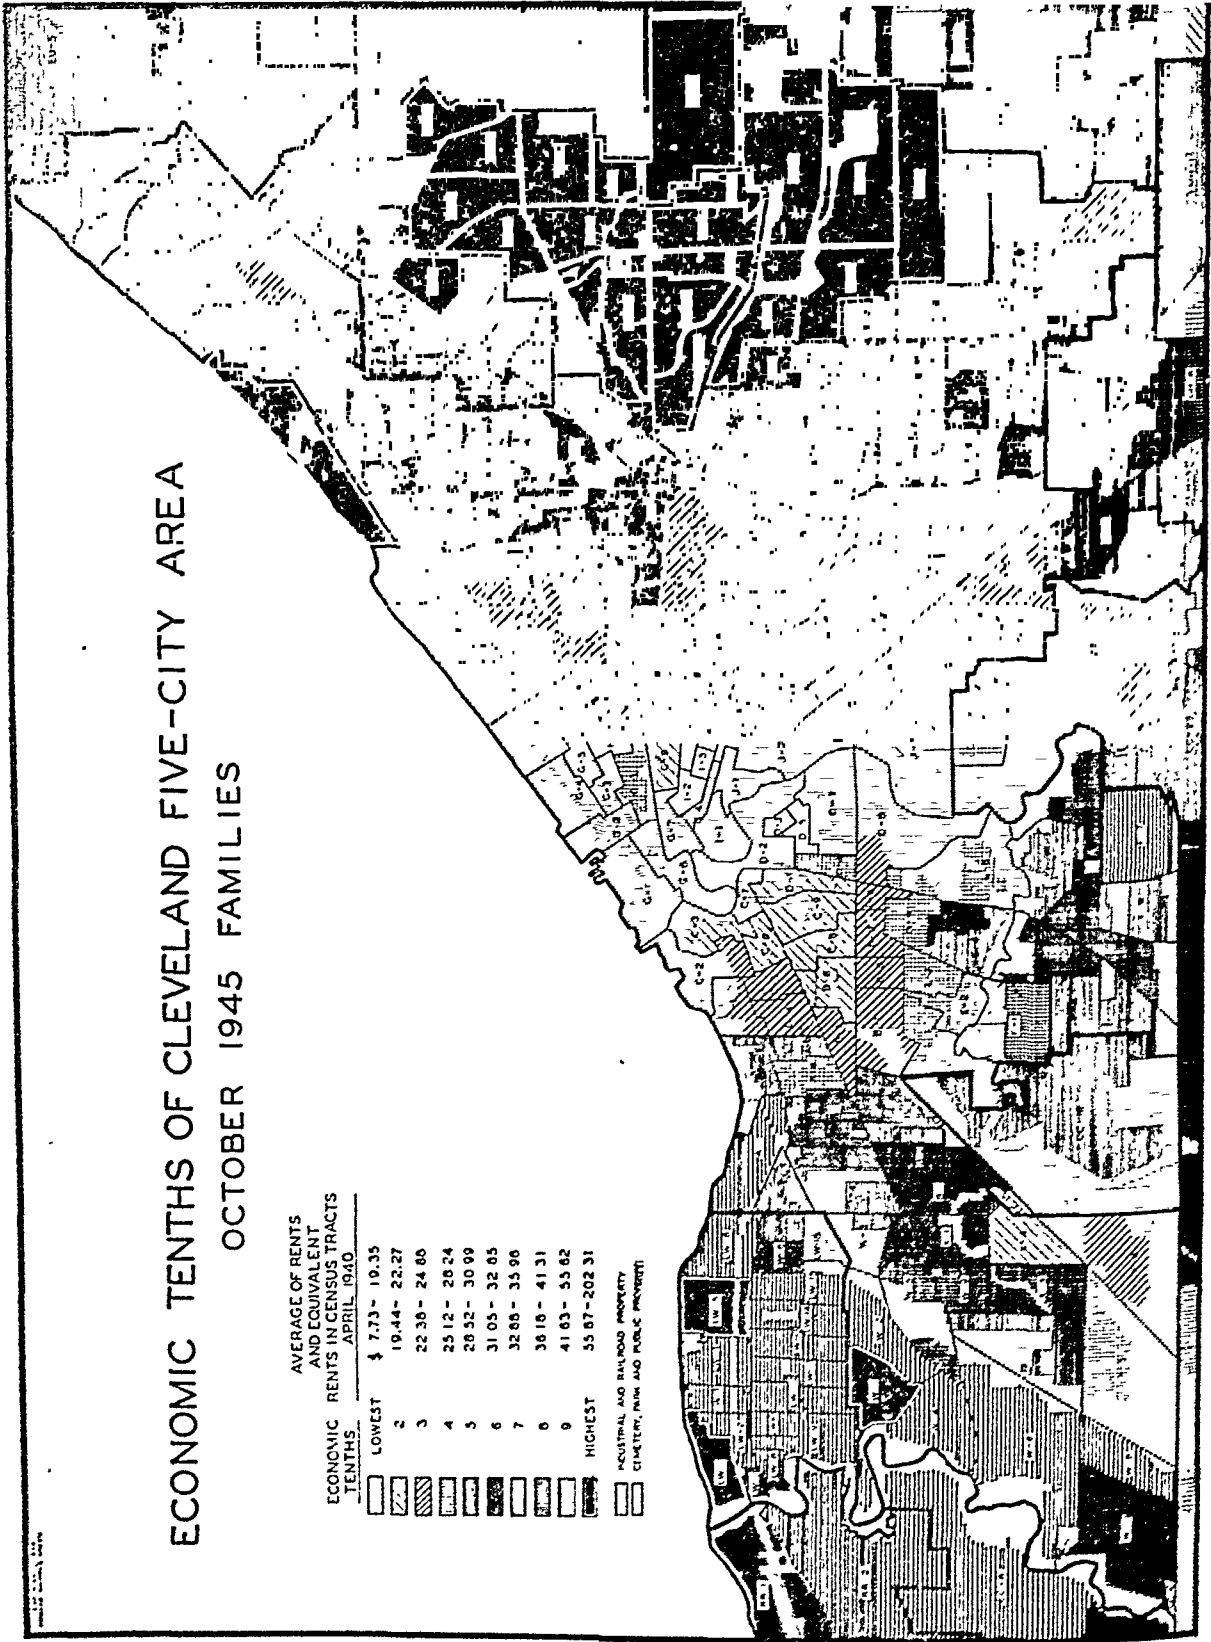

The median number of years of school completed by persons 25 years of age and over was 8.7 for the entire Cleveland five-city area in April, 1940, less

than 7 years in the lowest economic tenth and more than 12 years in the highest economic tenth.

Table 2 shows the figures for each economic tenth.

The percentage of births in hospitals or deliveries by midwives in 1919 varied by economic tenths. Less than a fifth, 19 per cent, of the births in the Cleveland five-city area were in hospitals in 1919, 5 per cent of those in the lowest economic tenth and 53 per cent of those in the highest economic tenth.

More than three-quarters, 76 per cent, of the births in the Cleveland five-city area were in hospitals in 1937, 59 per cent of those in the lowest economic tenth and 98 per cent of those in the highest economic tenth.

Nearly one-third, or 32 per cent, of the births in the Cleveland five-city area were delivered by midwives in 1919, 62 per cent of those in the lowest economic tenth and 5 per cent of those in the highest economic tenth.

In 1937 only 1 per cent of the births were delivered by midwives.

Infant mortality rates varied greatly by economic tenths in 1919.

The white infant mortality rate for the Cleveland five-city area in 1919 was 83. It varied from 116 in the lowest economic tenth to 45 in the highest economic tenth.

The white infant mortality rate for the Cleveland five-city area in 1937 was 40. It varied from 52 in the lowest economic tenth to 32 in the highest economic tenth.

Only slight variations by economic tenths were indicated for those under 1 month of age.

The variation of deaths of infants in the last 11 months of the first year of life per 1,000 live births in 1919 was spectacular and still great in 1937 even though the infant mortality rate was much lower.

The number of white infant deaths 1 month to 1 year per 1,000 live births in the Cleveland five-city area in 1919 amounted to 48. It varied from 78 in the lowest economic tenth to 16 in the highest economic tenth.

The number of white infant deaths 1 month to 1 year per 1,000 live births for the Cleveland five-city area in 1937 amounted to 13. It varied from 26 in the lowest economic tenth to 5 in the highest economic tenth.

Table 3 shows these data for each economic tenth.

Cases of tuberculosis varied tremendously by economic tenths in 1930, and the variations were still great in 1940. In May, 1940, there were 5,767 cases of tuberculosis on record in the Cleveland five-city area, 924 in the lowest

8	334	45	46
9	269	29	27
Highest	166	33	27

economic tenth and 166 in the highest economic tenth.

The death rate from tuberculosis for Negroes varied between economic tenths in a manner similar to that for the white population. It was five times as high as the white rate in each economic tenth where there were enough Negroes to make such a comparison valid.

The number of new cases of tuberculosis discovered in case finding clinics in 1945 in the Cleveland five-city area totaled 761, and varied from 192 in the lowest economic tenth to 33 in the highest economic tenth.

A total of 894 cases were admitted to Sunny Acres Sanatorium and Lowman Pavilion of City Hospital in 1945, varying from 235 in the lowest economic tenth to 27 in the highest economic tenth.

Public health workers for years have recognized that with infant mortality rates varying greatly between states, the chance of causing reductions in the rates for the country was good. They also recognized that since infant mortality rates varied greatly between counties within a state, the chances of causing reductions in the state were good.

The county in which Cleveland is located has a population larger than any one of 17 states or the District of Columbia and larger than 4 entire states taken together. Therefore, the variations in rates within such a county may well be studied.

I have shown you that certain mortality and morbidity rates vary greatly between sections of the Cleveland community, and therefore the chances of successfully causing further reductions in the rates for the entire community are good.

Such analyses make it possible to concentrate public health activities in areas with high rates. Such analyses make it possible for the health officer to use a rifle rather than scattering his fire with a shotgun.

The Correlation of Laboratory and Clinical Evidence of Virulence of *C. diphtheriae**†

MARTIN FROBISHER, JR., Sc.D., F.A.P.H.A.,
ELIZABETH I. PARSONS, Sc.D., AND ELAINE UPDYKE, Sc.D.

Department of Bacteriology, Johns Hopkins University, School of Hygiene and Public Health, Baltimore, Md.

SINCE the work of Loeffler, and of Roux and Yersin about 1890, it has been generally accepted that strains of *Corynebacterium diphtheriae* which produce soluble exotoxin are capable of producing diphtheria in susceptible human beings. There seems no reason at present to alter our view on this point.

With respect to strains which do *not* produce soluble exotoxin, it was first recognized by Loeffler that certain cultures of *C. diphtheriae* obtained from normal persons are not "virulent" as judged by tests in rabbits or guinea pigs. While some of Loeffler's non-virulent strains were doubtless what we now call diphtheroids, i.e., *Corynebacterium xerose* and *Corynebacterium pseudodiphthericum* (Hoffman's bacillus), it has been repeatedly confirmed that there are many strains of *C. diphtheriae* which are entirely avirulent (i.e., non-toxigenic) as tested in animals, but otherwise absolutely indistinguishable from virulent (i.e., toxigenic) *C. diphtheriae*, either morphologically

or on any known cultural or biochemical basis.‡ After the classical studies on diphtheria by Roux and Yersin, it was assumed, and at the time justifiably so, that these non-toxigenic strains could not cause clinical diphtheria.

However, within the last two decades, from time to time, here and there, doubt has been expressed as to the absolute soundness of the time-tested doctrine that strains of *C. diphtheriae* which give a positive virulence test in animals can cause diphtheria, while those giving a negative virulence test cannot cause diphtheria. In 1922 Jordan, Smith, and Kingsbury¹ stated, on the basis of a careful comparative study, that pathogenicity of diphtheria bacilli for human beings and for guinea pigs are not absolutely parallel. A little later Doull² brought the value of the animal virulence test as a clinical method into question on a statistical basis. In evaluating the danger, to a susceptible person, of exposure to cases, contacts of cases, casual healthy virulent carriers, carriers of avirulent organisms, and the general population, he found a definite

* Presented before a Joint Session of the Health Officers, Epidemiology, and Laboratory Sections of the American Public Health Association at the seventy-fourth Annual Meeting in Cleveland, Ohio, November 11, 1946.

† The studies on immunity and endotoxin referred to in this paper were carried on with financial assistance from the International Health Division of The Rockefeller Foundation.

‡ The terms virulent and avirulent (or non-virulent) as used here, refer to production or non-production of a soluble exotoxin demonstrable in sterile filtrates of broth cultures of such organisms.

and unexpected excess of cases among contacts of carriers of avirulent strains. This could be explained only on the basis that: (a) the bacteriologist was in error or, (b) that the virulence test in animals failed to reveal fully all the pathogenic potentialities of all strains of *C. diphtheriae*, including possible change of avirulent to virulent and reverse. The first explanation (a) appears to have been generally accepted. At any rate, no further attention was given to the matter on an experimental basis.

The possibility cannot be denied that virulent organisms may completely lose their virulence. The change appears to be rare, and if it occurs, is nearly always accompanied by such profound alterations in morphological and biochemical properties as to suggest contamination or at least to render impossible identification of the strain if its source is not stated. Changes of this sort have been reported by Crowell,³ Cowan,⁴ and Maver.⁵ Morton⁶ reported more convincing changes. The epidemiological studies by Dudley, *et al.*,⁷ in 1934, present merely circumstantial evidence for loss of virulence, which is far from convincing.

On the other hand, extensive investigation by Ramon, Débre and Gilbrin⁸ in Paris, by Okell,⁹ Okell and Parish,¹⁰ and Dudley,¹¹ in London, by Powell,¹² and by ourselves (unpublished) in Baltimore, have failed to reveal any instance in which virulent strains, while retaining their typical morphological and biochemical properties, have become avirulent. Conversely, avirulent strains, under the same conditions as to identifying characters, have never been proven to acquire the property of toxigenicity. It is of especial interest, therefore, that non-toxicogenic strains of *C. diphtheriae* continue to force themselves upon our attention as possible agents of disease, possessed of some subtle, unexplained, pathogenic power.

VIRULENCE OF NON-TOXIGENIC DIPHTHERIA BACILLI FOR MICE AND CHICK EMBRYOS

Light on the question of pathogenic properties of avirulent diphtheria bacilli was first focused from a somewhat oblique angle when it was discovered in 1940¹³ that cultures of *C. diphtheriae* absolutely devoid of the power of producing exotoxin, so far as could be determined by the most sensitive tests, would kill mice regularly following intracerebral injection. Direct tests of toxigenicity by subcutaneous injection of large doses of live culture into guinea pigs were entirely negative, and delicate tests in guinea pigs allergic to toxin¹⁴ confirmed the non-toxigenicity of the cultures. Ordinary antitoxin had no protective effect whatever against the intracerebral effects in mice. The extraordinary and highly distinctive signs of cerebral irritation in mice dying of

FIGURE 1—Mice after injection of non-toxicogenic diphtheria bacilli intracerebrally. The animal in the center was moribund. Note the curious position of head and fore part of the body, and the crooked tail; both are distinctive of the endotoxic encephalitis.

such injections have been previously described.¹⁵ Peculiar paralyses and evidences of peripheral neuritis are an outstanding feature (Figure 1).

The effect of the avirulent organisms on mice was first ascribed to irritation due to infection, and probably infection does exist for a time before the mice die, which usually occurs in about 4 to 8 days. However, it has not been possible to carry the infection from brain to brain more than a maximum of four daily or 2-day transfers; usually we could not produce any symptoms in third-passage mice and the organisms died out and could not be recovered in cultures. Smears from the brains showed that the bacteria were actively phagocytized. Whether or not infection (i.e., considerable proliferation of the organisms in the brain) existed, the distinctive signs of cerebral irritation produced by these organisms were not reproducible with other bacteria which also killed mice by intracerebral injection, such as typhoid bacilli and pneumococci, and they were therefore ascribed to the effects of specific endotoxins peculiar to the avirulent diphtheria organisms. Heat-killed or ground-up diphtheria bacilli, virulent or avirulent, had no such effect. Dudley¹¹ has noted similar endotoxic effects in guinea pigs.

T'ung¹⁶ showed that avirulent strains could invade chick embryos and even induce the formation of histologically typical pseudomembranes on the chorio-allantoic membrane.

It was illuminating to discover also during these studies that sterile, filtered exotoxin from toxigenic strains of *C. diphtheriae* produced an identical clinical picture in mice, but that *it could readily be controlled with antitoxin*.

ATOXIGENIC BACILLI AS IMMUNIZING AGENT

Another source of light on the possible significance of endotoxins was kindled in 1936 and 1940 when it was

found in Alabama by Chason¹⁷ and by Gill¹⁸ during studies of the prevalence of carriers of virulent diphtheria bacilli, and the relation of such carrier rates to the Schick test, that 90 to 92 per cent of rural children *under 10 years of age* were Schick-negative while virulent-bacillus carrier rates were under 1 per cent. But it was found in 1940 that about 7 per cent of the children carried avirulent bacilli. Even more striking data of a similar nature were found by Stebbins¹⁹ in Kingston, N. Y.

In attempting an explanation of these findings it was suggested that the role of the widely prevalent avirulent organisms might be that of an immunizing agent.²⁰⁻²² While not capable of inducing Schick-negativeness, since that depends on antitoxin, it could increase resistance so that a Schick-negative status could be attained by many children in the population as a result of contact with virulent bacilli with little or no evidence of clinical diphtheria. Without offering any defense of this hypothesis, we nevertheless thought of attempting immunization of rabbits and guinea pigs with suspensions of live, avirulent, non-toxigenic diphtheria organisms and testing the resistance of the animals to live, virulent, toxigenic strains and to sterile toxin.²³ The details of later studies of immunization will be published later.

About 64 per cent of the immunized animals showed definite resistance to sterile toxin, or to an infective dose of live organisms which has never failed to kill control animals, of which several dozen have been used, within 1 to 5 days. This very severe test of resistance greatly exceeds the type of infection encountered in the ordinary course of human contacts. It was used because it was found very difficult to adjust smaller doses so that a reasonably constant lesser percentage of control animals would die. So variable is the resistance of the test animals to border-

TABLE 1
Resistance of Animals Immunized with Avirulent Diphtheria Bacilli

Animals	Injected	Survived	Significantly Outlived Controls (Beyond 7 Days)	Showed Some Evidence of Resistance
Rabbits	22	8	3	11 (50%)
Guinea pigs	80	39	15	54 (67.5%)
Totals	102	47	18	65 (64%)
Controls (20 rabbits and 25 guinea pigs)	45	0	all died 2-5 days	0

line lethal doses that, to accomplish this, an unduly large number of animals would have to be used in order to obtain a statistically valid result. It is felt, therefore, that the resistance manifested by the immunized animals, even though it may not have saved all of them, was effective to an extraordinary degree. About 20 per cent of the immunized animals survived. These data are summarized in Table 1. Animals tested were found Schick-positive at the end of the period of immunization. In none of them was even so small an amount as 0.001 unit of antitoxin per ml. of serum demonstrable. This absence of antitoxin has been repeatedly and thoroughly confirmed. Indeed, the serum of resistant animals assayed either by skin test or by *in vitro* titration, had no demonstrable specific antibody content whatever except for agglutinins in low titer. Additional details of some of these tests are to be published elsewhere.

OCCURRENCE OF NON-TOXIGENIC BACILLI IN CLINICAL DIPHTHERIA

Knowledge stood at this level in 1945 and 1946 when very disturbing results began to be obtained from virulence tests made on cultures obtained from patients in Sydenham Hospital in Baltimore. Cultures were handled, and all tests carried out, in a manner rigidly conforming in all respects to procedures followed during the last 14 years in studying diphtheria bacilli in this laboratory. We have, therefore, no reason to suspect that aberrant results may have been due to irregularities in labo-

ratory technics. Yet there seems no question that repeatedly during the last 2 years, and with increasing frequency, we have isolated from undoubted cases of clinical diphtheria, diphtheria bacilli which are wholly atoxigenic, or totally avirulent, as judged by tests in both rabbits and chicks.²⁴ These observations are paralleled by findings reported to us from other parts of the United States and observed in other countries where we have studied diphtheria.

DISCUSSION

There appears to be no doubt of the validity of the facts observed. As to explanation, we may, as it were, "pleasantly speculate" or, if we wish to flatter our astuteness, "shrewdly guess" on the basis of available facts: (1) We know that avirulent diphtheria bacilli contain an endotoxin. (2) We know that this endotoxin and exotoxin produce identical symptoms in mice, and that both are strongly neurotropic; also there is evidence that avirulent organisms can induce pseudomembrane formation in chick embryos. (3) We know that endotoxin is immunologically related to exotoxin since we can produce resistance to infection or intoxication by one with injections of the other. (4) We know that cases of clinically typical diphtheria occur in which only non-toxicogenic bacilli are found.

On the basis of these facts, we may reasonably hypothesize that endotoxin plays some role in the pathogenesis of some cases of diphtheria. The suggestion is made that it may be a precursor

of exotoxin, just as certain pigments of bacteria or digestive enzymes of other cells are precursors intracellularly of what they become extracellularly. For example pyocyanin, excreted as a leucobase, becomes blue on oxidation, while pepsin first appears as pepsinogen. If this idea be permitted, we may suspect that at least some strains of so-called avirulent diphtheria bacilli liberate considerable amounts of endotoxin as such—perhaps on disintegration due to lytic action of the phagocytic cells or of the serum of the patient. Following the pyocyanin and pepsin analogy, this endotoxin, once liberated, could become activated (possibly oxidized) to something like exotoxin by the tissues with which it combines, resulting in damage to the tissue cells.

We know that ordinary antitoxin has no effect on the endotoxin, at least in mice. It is conceivable that in cases of *endotoxic diphtheria*, if indeed they occur, antitoxin would be of less avail than usual, because it could not affect the endotoxin till it was activated by combination with tissue cells, and then, as is generally known, it would be too late for antitoxin to neutralize it.

Obviously, more clinical investigation is needed in correlation with laboratory studies to determine: (1) whether such cases are more or less refractory to antitoxin; (2) whether the serum or cells of such patients contain lytic bodies for avirulent diphtheria bacilli; (3) whether all so-called avirulent strains are alike in endotoxin content, both qualitatively and quantitatively (we have evidence indicating differences in this respect). (4) Chemical studies on the relation of *endotoxin* and *exotoxin* would be of great interest.

IN SUMMARY

We have cited evidence, first, that "virulence tests" of diphtheria bacilli in rabbits, chicks, and guinea pigs (which are merely tests for production

of exotoxin) do not necessarily reveal all pathogenic potentialities of diphtheria bacilli for human beings.

Second, it is clear that so-called avirulent diphtheria bacilli contain endotoxins.

Third, we have evidence that endo- and exotoxins of *C. diphtheria* are immunologically related, but that the endotoxin is not neutralized by anti-exotoxin.

Fourth, in numerous cases of clinically typical diphtheria only non-toxicogenic strains of diphtheria bacilli have been found.

It seems reasonable to conclude that avirulent diphtheria bacilli may be implicated in some way in the production of diphtheria-like disease.

Present Recommendations Concerning Treatment and Prophylaxis of Diphtheria*

FRANKLIN H. TOP, M.D., M.P.H., F.A.P.H.A.

Medical Director, Herman Kiefer Hospital, Detroit, Mich.

THERE is at the present time a re-awakened interest in diphtheria, stimulated by a slight rise in case incidence in areas throughout the world where the disease is indigenous and augmented by a disproportionate increase of cases among adults, both civilian and military. The rise in case incidence, however slight, has been viewed with alarm, particularly by health officers, who felt they had in diphtheria immunization a formidable weapon for the control and elimination of diphtheria; and by clinicians, who felt they had in diphtheria antitoxin the answer to treatment problems. A progressive decline in diphtheria over the past two decades has had a lulling effect on some communities with a resultant lukewarmness in diphtheria prevention. Implements for prevention and treatment are available, but adequate utilization is necessary. The historical background of both treatment and prophylaxis will be largely omitted, as others have performed this task both capably and exhaustively.

TREATMENT OF DIPHTHERIA

The clinical classification of diphtheria by type is, in general, uniform in the United States, Canada, and Eng-

land, and is based on anatomical involvement. In Germany the classification is on the basis of clinical severity; anatomical involvement being considered secondary. On an anatomical basis and in order of severity from mild to severe, clinical types are as follows:

Nasal—Involvement of the anterior nares—little toxin absorption.

Tonsillar—Membrane on one or both tonsils—moderate toxin absorption.

Pharyngeal—Membrane present on the posterior wall or fauces, generally occurring in a person whose tonsils have been removed—toxin absorption moderately severe.

Nasopharyngeal—Involvement of the mucous membrane of the posterior nares, upper pharynx, and tonsils—toxin absorption severe.

Laryngeal (three types):

Primary—Sole involvement in the larynx—toxin absorption minimal.

Tracheobronchial—Involvement of the trachea, the bronchi, the smaller bronchioles, and occasionally the alveoli—toxin absorption moderate.

Mixed—Involvement of larynx plus extension downward, to involve the trachea and bronchi, or upward, to involve the nasopharynx or tonsils, occasionally beginning as tonsillar or nasopharyngeal and extending to the larynx—toxin absorption varied depending upon degree of involvement of nonlaryngeal structures.

Treatment of Types—Diphtheria is largely a local process with toxin elaborated at the site of infection and distributed throughout the body via the blood stream. In the gravis type of

* Presented before a Joint Session of the Health Officers, Epidemiology, and Laboratory Sections of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 11, 1946.

diphtheria, invasiveness is reputedly increased. Irrespective of type of organism, or degree of invasiveness, main reliance in the treatment of diphtheria is on the early use of antitoxin. Antitoxin remains the most important therapeutic weapon, and the dictum still holds that prognosis in diphtheria is dependent upon the day of disease that antitoxin is first given. In general, gravis infections encountered in Europe during the past few years have been amenable to antitoxin if given in sufficient amount and early in the course of the infection.

The amount of antitoxin necessary for treatment is still debatable. When antitoxin was first used in the treatment of diphtheria, there were two schools of thought regarding the dosage. One school held that small amounts were ample while the other considered a large amount necessary, given in one or two massive doses. Later, the French introduced the small multiple dose method. With relation to present-day treatment of diphtheria, most infectious disease clinicians would be classified in the large dosage group. Actually, 4,000 units of diphtheria antitoxin are ample to neutralize the free or floating toxin in the blood at any given moment. Some toxin is already fixed to tissues which have a predilection for it, such as heart muscle and nerve tissue, and this situation antitoxin does not remedy. If the infection is of more than average severity, toxin continues to form until the reparative forces of the body can destroy diphtheria bacilli, and excess antitoxin is necessary to neutralize quickly newly formed toxin. In order to accomplish this a large dose of antitoxin is given.

In Germany, in the spring of 1946, as little as 2,000 units of antitoxin were given in the treatment of a mild case and 20,000 units as a maximum dose in a severe case. German clinicians who preferred to give more than 50,000

units of antitoxin stated that they could not give more on account of a shortage. Two eminent physicians in Munich, with communicable disease experience extending over twenty years or more, stated that during World War II necessity limited their use of antitoxin to 50,000 units in the most severe case, and it was their considered opinion that such an amount was sufficient. In London the dosage varied between 10,000 and 120,000 units among the majority of fever hospital heads; however, one was encountered who used a minimum of 40,000 units to a maximum of 250,000 units. The minimum amount of antitoxin used at the Herman Kiefer Hospital is 20,000 units and the maximum 120,000 units. I believe that we have probably been using too much antitoxin, which can be considered less harmful than not enough, but in general 60,000 units should be sufficient, because the case recognized early needs less, whereas in the late case much toxin is already fixed by tissues, and an excess of antitoxin is valueless. In general, the amounts used by clinical type at the Herman Kiefer Hospital are as follows: nasal 10,000 units; tonsillar—unilateral 20,000 units, bilateral 20,000–40,000 units; nasopharyngeal 60,000–100,000 units; laryngeal—primary 20,000 units, tracheobronchial 40,000 units; mixed 40,000–100,000 units.

Route of Administration—There is a difference of opinion regarding the route of administration, but in severe cases at least some of the antitoxin should be given by the intravenous route. The plan for a maximum dose of 80,000 units would be as follows: 40,000 units intramuscularly and 40,000 units intravenously. It would be desirable, if safe, to give the intravenous dose first, in order to neutralize the non-fixed toxin in the blood as quickly as possible, but serum sensitivity must be considered. It is necessary to obtain a history of sensitivity to horse

serum, horse dander, or in fact any allergy, and also to do a skin test to determine sensitivity to serum before administration by any route. At present most diphtheria sera are despeciated; that is, by enzymatic or pepsin digestion, nearly all of the albumen fraction has been removed, eliminating most of the reactions previously encountered. However, exceedingly sensitive individuals may still be sensitive to very small amounts of horse protein. If there is a history of sensitivity, a skin test should be given, using 0.01 ml. of raw horse serum intracutaneously; with a negative history 0.1 ml. intracutaneously. The test should be read at the end of 20 minutes, and, if negative, serum may be given intramuscularly, followed in 2 hours by an intravenous test dose of 1 ml. of serum in 9 ml. of 10 per cent glucose or distilled water, and if no reaction occurs, the intravenous dose may be given. Penicillin appears to have bacteriostatic value *in vitro* but is not of value in neutralizing toxin. If a highly sensitive person is encountered or if complications occur due to a secondary invader, or if the infection is multiple (such as simultaneous diphtheria and streptococcus infections), penicillin should be used in amounts of 50,000 Oxford units stat and 30,000 Oxford units every 3 hours for 5 days or more. In the instance of sensitivity, penicillin should be given, desensitization should be carried out, and antitoxin administered; for there is absolutely no substitute for antitoxin in the treatment of diphtheria.

Management Other Than Administration of Serum—All diphtheria patients, with the exception of cases of the nasopharyngeal and laryngeal forms, can be safely removed from isolation at the end of 10 days or 2 weeks if recovered and if nose and throat cultures are negative. In the instance of laryngeal cases, unless a tracheotomy has been performed, and in the ab-

sence of complications, 10 days' to 2 weeks' stay in hospital is sufficient. The nasopharyngeal type should always be hospitalized and remain in hospital for a minimum of 42 days, extension of time depending upon the duration of severe complications, such as myocarditis early in the disease and nerve palsies which occur generally between the 15th and 35th day of convalescence.

PROPHYLAXIS

It has been amply demonstrated that immunization against diphtheria is of value, although the marked decrease in incidence over the past twenty years cannot be entirely credited to this procedure. A number of antigens have been used during the past two decades, notably toxin-antitoxin, plain toxoid, and alum-precipitated toxoid. Toxin-antitoxin was the agent most commonly used in the early days of diphtheria immunization. Parke¹ showed conclusively that three injections of 1 ml. each, given at intervals of one to two weeks, protected 85 per cent of those injected. Immunity developed within 3 to 6 months, but reactions followed the injection of this material, reputedly due to bacterial protein in the toxin; also antitoxin in the mixture caused sensitization to horse serum. In an attempt to decrease toxicity, Ramon² produced formal toxoid in 1923, which accomplished the purpose without losing immunizing property. Under field conditions, giving two doses at intervals of 2 weeks, protection was afforded 80 to 90 per cent of those injected, while three injections protected over 90 per cent. Protection occurred more promptly than was noted following the use of toxin-antitoxin. However, plain toxoid also caused reactions.* Further

* Sensitivity to toxoid can be determined by the intracutaneous injection on the forearm of 1/10 ml. of a 1-20 dilution of plain toxoid (Moloney test). Sensitivity can also be determined by the pseudo or false Schick reaction but is not so reliable.

purification of diphtheria toxin was accomplished by Glenny and his associates³; they produced an alum-precipitated toxoid by precipitating plain toxoid with aluminum hydroxide. In the majority of field trials one dose of this material produced a Schick-negative status in over 90 per cent of inoculated children in from 6 weeks to 3 months. These early protection rates did not hold in the face of a declining case incidence, with the result that two doses were advocated with the interval 1 month or 6 weeks. Reactions occurred after injections with the alum toxoid; these were considered the result of sensitization to bacterial protein. Occasionally a sterile abscess or antigen cyst developed. Protection following the use of alum-precipitated toxoid appeared to occur more readily than after the use of the aforementioned antigens.

There were other antigens available for use; perhaps the most notable among which was TAF (toxoid, antitoxin flocules), prepared by Glenny and Pope,⁴ rather widely used in Great Britain but uncommonly so in the United States and Canada. The antigen appeared less likely to produce reactions than those more commonly used; but from some reports at least, suffered from somewhat weaker antigenic power, and the fact, as with toxin-antitoxin, that it contained antitoxin which, in spite of refined and despeciated sera, still sensitized to horse serum. TAF could be used for older children and adults who were Moloney-positive, in three doses of 1 ml. at not less than 2 week intervals, as advocated by Harries.⁵

Choice of Immunizing Agent—Particularly during the past decade, studies have been carried out in many places with the idea of determining the most suitable immunizing agent, the correct dose, the number of doses, and the desirable age at which the agent may be safely given. It has been the objective of the Subcommittee on Diphtheria, of

the Committee on Administrative Practice of the American Public Health Association, to evaluate by field trials certain protective substances, and by their sponsored investigations to determine at first hand the agent of choice. From the results of extended studies, Volk and Bunney⁶ concluded that in children with less than 0.001 unit of antitoxin per ml. of serum at time of injection, two doses of A.P.T. (alum-precipitated toxoid) at 3 week intervals gave the best antigenic response. In decreasing order of value were the following: three doses of F.T. (fluid toxoid) at 3 week intervals; one dose of A.P.T.; two doses of F.T. at a 3 week interval, and one dose of F.T.

Fraser and Halpern⁷ preferred three doses of P.T. at 3 week intervals. Chesney,⁸ using two doses of A.P.T. with a 4 week interval, produced a Schick-negative rate of 99.6 per cent in 1,555 inoculated children 2 months after injection of the second dose. It would appear from these studies and numerous others that A.P.T. in two doses at 4 to 6 week intervals, is the antigen of choice for children susceptible to diphtheria. The dose of A.P.T. in the United States is generally 0.5 ml. for each injection, whereas in Great Britain it is likely to be 0.2 and 0.5 ml.

Older children and adults, to whom plain toxoid or alum-precipitated toxoid is to be administered, should first be given a Moloney test, and if no skin reaction is noted within 24 to 48 hours, the toxoid may be safely administered. A.P.T. is the antigen of choice if smaller and more numerous doses are feasible. Instead of two doses of 0.5 ml. at monthly intervals, the following doses may be given at the same interval: 0.1, 0.3, and 0.5 ml. A severe reaction to any of these injections should result in discontinuance, as it is likely that reacting individuals have had previous experience with the organism, and the amount already given would cause

ample antigenic response. A common reaction is stinging or pain at the site of injection, which usually appears within 1 hour. A generalized reaction, accompanied by chills, headache, fever, or vomiting may occur.

Recently, Ross⁹ has advocated the use of protamine diphtheria toxoid for older children and adults as well as for infants, to obviate reactions. He found that this product produced on infrequent occasions a slight erythema and induration. Field trials by Ross¹⁰ and his associates indicated that 2½ to 18 months after a single subcutaneous injection of protamine toxoid, the antitoxin content of the blood in 78 per cent of young children was between 1/100 and 1/5 of a unit. When two doses of toxoid were injected, 79 per cent of the children had 1/10 of a unit some 2½ to 3 months after the second dose, and 60 per cent had 1/5 of a unit or more. Further field work is necessary to evaluate this antigen.

Optimum Age for Injection—It is recommended that all infants should be injected between the ages of 9 months and 1 year. A Schick test should be performed 6 months after completion of injection, and, if positive, another dose of toxoid should be given. Just prior to admission to school the Schick test should be repeated to determine the susceptibility of the child at that time. Those found non-immune should be reinjected; better still, the Schick test may be dispensed with and a "booster" or reinjection dose of plain or A.P. toxoid given. Jensen,¹¹ Fraser and Halpern,¹² Duke and Stott,¹³ and Volk and Bunney¹⁴ have emphasized that regardless of immunizing procedure, diphtheria immunity is not permanent. With time the amount of antitoxin in the blood diminishes. For this reason reinjection is necessary at certain intervals.

Reinjection against diphtheria has been studied by Volk, Bunney, and

Tripp.¹⁵ They find that reinjection with P.T. or A.P.T. is highly effective, the latter slightly more so than the former. One small "booster" dose produced a satisfactory response with no allergic reaction observed among a group of 808 children. Local reactions were not severe enough to discourage reinjection. Wilkey¹⁶ has concurred in the value of a small dose of plain toxoid as a reinforcing dose.

The *method of injection*, subcutaneous or intramuscular, and the *site*—deltoid area—have been widely used for the injection of diphtheria antigens. Other routes have been utilized, however. Jensen,¹⁷ Fraser, Davey, and Halpern,¹⁸ and Phair¹⁹ have injected individuals by means of nasal instillation of toxoid. Blatt, Fisher, and van Gelder²⁰ have used the intradermal method, giving a dose of 1/10 ml. of plain or alum-precipitated toxoid and reporting good results. Others have advocated the intradermal method for reinjection. The intranasal method may lead to untoward reaction as Anderson²¹ and Phair¹⁹ have reported. Both methods need further study to warrant practical and statistical assessment.

SUMMARY

1. Antitoxin is the agent of choice in the treatment of diphtheria, and prognosis is still directly proportional to the day of the disease that antitoxin is first given, regardless of type of organism encountered, though the gravis type infection may be more refractory to treatment.

2. Penicillin is not a substitute for antitoxin but under certain circumstances is an adjunct in the treatment of diphtheria.

3. Among antigens available for protection against diphtheria, A.P.T. is the agent of choice, given in two doses at intervals of 1 month to 6 weeks.

4. In the presence of a declining case and carrier incidence, "booster" doses of antigen are necessary. "Booster" doses of A.P.T. are suggested at 2 years of age, and again before entering school for the first time. Thereafter, an unusual incidence of the disease in the community warrants further antigenic stimu-

lation, proceeding with caution and using plain toxoid after the age of ten to twelve years.

Water Supply

Engineering Section

THIS committee submitted a report before the Engineering Section at the 1944 meeting of the Association. We endeavored at that time to appraise wartime developments in connection with public water supplies which appeared to have had a peacetime significance. In the meantime, certain trends have been established. It is our purpose at this time to discuss current aspects of water supply control of special interest to the public health field. Some aspects of our discussion will be elementary or self-evident to specialists, but they are being reviewed to focus attention upon the administrative implications which may be overlooked in the preoccupation with technical matters. It is believed that this is an opportune time to state the objective of this committee, namely: *safer water supplies*. To this end, the committee is devoting its attention to the following:

1. The determination of what diseases are now transmitted by potable water supplies
2. Proper treatment of water to eliminate these diseases
3. Proper tests to determine when this has been accomplished
4. The proper training of personnel to insure effective operation and control and thus give maximum protection to the consumer by insuring the delivery of water of safe sanitary quality

Present trends and events in the field of public water supply of special interest to public health workers appear to be as follows:

FREE RESIDUAL CHLORINATION

There is a lag between the development and refinement of technical processes, laboratory technique, etc., and their application in the routine treatment and supervision of public water supplies. This is emphasized by the present status of chlorination for the production of free residual chlorine; that is, superchlorination or break-point chlorination. In spite of the extensive literature upon the subject and in spite of the rather numerous supplies which are being subject to free residual chlorination, there is still a reluctance on the part of many water supply officials to avail themselves of this treatment process. It seems pertinent, therefore, to focus attention upon the fact that the use of chlorine doses sufficient to give free residual chlorine rather than combined residual chlorine (chloramines) will result in the following advantages:

1. Effective disinfection in spite of the adverse influences of short detention period, high concentration of organic matter and free ammonia, high pH values, and lower water temperatures
2. The production of free residual chlorine which is stable and generally tasteless, although high concentrations of free residual chlorine may produce a detectable chlorinous odor
3. The destruction by oxidation of taste and odor producing compounds
4. The control of growths in water mains
5. The prevention of biochemical corrosion of water mains through the destruction of organisms
6. The prevention of the biochemical reduction of sulfates to sulfides

COMMITTEE ON WATER SUPPLY

Organized 1922. Published reports: *A.J.P.H.*, Sept., 1924, Apr., 1925, Feb., 1926, July, 1927, Apr., 1928, Feb., 1929, May, 1930. *Year Books* 1930-1931, 1931-1932, 1932-1933, 1934-1935, 1937-1938, 1939-1940, 1940-1941, 1941-1942, *A.J.P.H.*, July, 1945.

In addition to the above advantages of superchlorination, the following results are of special significance because they may be secured in the absence of filtration when a sufficient detention period is available in a reservoir or basin. These effects are as follows:

1. The bleaching of color
2. The precipitation of iron and manganese
3. The coagulation of soluble organic matter
4. The control of algae and other organisms

While the qualitative flash test for free residual chlorine has not given consistent results, the quantitative orthotolidine-arsenite (OTA) test provides a simple technique for the control of chlorination for the production of chemically active, free residual chlorine, and also for the rational control of the use of ammonia in those few instances where the practice of chloramination still may be warranted in spite of the well established lower disinfecting powers of combined residual chlorine. The OTA test, therefore, may be considered as replacing the standard OT test for the general control of chlorination processes.

The disclosure of the marked difference in the disinfecting rates with free residual chlorine and combined residual chlorine, the development of the practice of free residual chlorination, and the availability of a test necessary for its rational control represent the most important development in the field of water disinfection since the standard orthotolidine test was developed many years ago. A major step in the improvement in the quality of public water supplies would result were the conditions surrounding chlorinated supplies, including chloramination,* reap-

praised in the light of modern chlorination technique and were the tests for free residual chlorine used as a routine for the more rational control of chlorination for disinfecting purposes and for the other benefits outlined above. We have the tools but we need to stimulate their more general use, especially for unfiltered supplies.

CHLORINE DIOXIDE TREATMENT

The use of chlorine dioxide for the destruction of taste and odor producing compounds, referred to in the 1944 report of this committee, is being used more generally. While additional experience is needed to establish this process of taste and odor control, it is significant that while chlorine dioxide itself does not disinfect water it does not interfere with the effectiveness of chlorination. If preliminary indications are confirmed by more experience, chlorine dioxide may prove to be an aid in disinfection by maintaining a higher oxidation potential. This is the converse of chloramination which provides an inhibited chlorination reaction.

THE FLUORINATION OF POTABLE WATER SUPPLIES

The application of sodium fluoride to public water supplies to minimize the incidence of dental caries was started in 1945 at Newburgh, N. Y., Grand Rapids, Mich., and Brantford, Ontario.

Subsequently this treatment process

much lower disinfecting power than hypochlorous acid. In fact, its disinfecting power is lower than an equivalent concentration of chloramines. Therefore the presence of free residual chlorine at high pH values does not disclose the same favorable disinfecting conditions as with low pH values. Chloramination of waters of high pH value, therefore, may be preferable to free residual chlorination, such as waters softened by the lime-soda process or waters treated with lime for corrosion prevention. Data as to experience with various waters are needed to permit a more intelligent appraisal of the field of usefulness of chloramination with waters of high pH value. In the meantime it seems evident that one should be critical of the effects of high pH values upon the disinfecting action of free residual chlorine.

* Unpublished data from the Harvard Engineering School disclose that free residual chlorine consists of hypochlorous acid (HOCl) and the ($-\text{O Cl}$) radical. One-half of the free residual chlorine is hypochlorous acid and one-half ($-\text{O Cl}$) radical at pH 8.0. The concentration of the latter increases with corresponding increases in pH value. Furthermore, these data disclose that the ($-\text{O Cl}$) radical has a very

has been started at Midland, Mich., Garrettsville, Ohio, and Marshall, Tex., and plans are being made for treatment of the supplies at Evanston, Ill., and Sheboygan, Wis., and certain supplies in Massachusetts and Oregon.

The cost of the demonstrations including special medical and dental supervision, laboratory work, etc., is very much greater than the cost of the treatment of water supplies in a routine manner. For instance, the demonstration at Newburgh, N. Y., is costing approximately \$25,000 a year for ten years, whereas the chemical feed equipment cost only \$350, and the cost of sodium fluoride for the treatment of 3,000,000 gallons of water per day is only approximately \$1,500 per year, or a per capita cost of 5 cents per year.

It is premature to determine the results of these demonstrations because it is well known that fluorine in potable water will exert a significant influence only upon the permanent teeth of children consuming such fluorine treated waters during the period of formation of the teeth. It is pertinent to remark, however, that no engineering problems have developed in the application of sodium fluoride to public water supplies of various sizes. The standard test for fluorine, while cumbersome, is satisfactory for the control of these studies, although the Lamar test¹ is favored for the control of the treatment of the ground water supply of Marshall, Tex., and a modified Elvove test is being used in Massachusetts which is claimed to be much faster and more satisfactory for field use. A simpler test, however, is needed for routine plant control.

Consumer reaction has been very favorable and in fact the tendency is for many municipalities to wish to introduce this treatment process prior to the development of basic scientific data through the technical experiments and demonstrations now under way.

DIATOMACEOUS EARTH FILTERS

While exhaustive studies as to the effectiveness and adaptability of these filters to meet the qualifications of the Engineering Corps, U. S. Army, have been conducted and while a few companies are manufacturing filter units of this type, so far there has been no record of the installation of diatomaceous earth filters for the clarification of public water supplies, except one city which has a \$25,000 experimental plant for the clarification of stored surface water. Such units, however, are being installed in limited numbers at artificial swimming pools. This should provide satisfactory opportunities for observing the effectiveness of the units in the hands of the average operator. One cannot overlook the fact that this development represents the only major change in filtration practice since rapid sand filtration was started. It would appear that this process of filtration with reduced plant size will be coördinated with current emphasis upon more thorough pretreatment. The process would seem to have special usefulness in the filtration of relatively clear surface water where prior coagulation is not so important. In fact, the schistosome cercariae were found to be removed by experimental diatomaceous filters without coagulation, whereas these very motile organisms will penetrate through sand filters. These findings are consistent with the results of experiments with the cysts of *Endamoeba histolytica*.

HIGH RATE FLOCCULATING AND CLARIFYING UNITS

The committee has little to report upon the effectiveness of these units in the treatment of waters of various characteristics other than that very satisfactory results have been secured through the use of relatively few installations made during the war. Over-all treatment periods of 1 to 1½ hours

for flocculation and clarification by upward flow through so-called sludge "blankets" or slurry are sufficient when the coagulant dose is satisfactory. Effective control, therefore, is essential to secure the advantages of this treatment method.

BACTERIOLOGICAL EXAMINATION OF WATER

In the ninth edition of *Standard Methods for the Examination of Water and Sewage*, no basic change has been made in the standard bacteriological tests for coliform organisms except that the choice of liquid media used in the alternate "partially confirmed test" is restricted to brilliant green bile. The production of gas in any amount in primary lactose broth tubes or in the secondary brilliant green bile tubes signifies positive results. There are those who object to accepting delayed or limited gas production as indicative of the presence of coliform organisms of sanitary significance. Furthermore, there are those who feel that brilliant green bile is not the most appropriate confirmatory liquid medium for use with certain classes of waters. Inasmuch as *Standard Methods for the Examination of Water and Sewage* generally is followed as a guide by water works laboratories, and as the 1946 revision of the *Drinking Water Standards* of the U. S. Public Health Service officially refers to the standard bacteriological technique as given in the latest edition of the methods, it is desirable for the administrative implications of these developments to be reviewed.

The text of the *Drinking Water Standards* provides for the exercise of administrative discretion in the interpretation of bacteriological results. That is, there is no need for blind acceptance of the results of the standard technique, but rather the attitude is encouraged to the effect that a positive test for coliform organisms indicates exposure of a

supply to pollution, or the existence of channels for the entrance of pollution into a supply, the sanitary significance of which must be determined by a survey to ascertain whether the pollution is likely to be accompanied by contamination of human origin. The exercise of technical judgment based on experience is necessary, therefore, to use this rather inclusive and therefore nonspecific test for bacterial pollution of water. For this reason, the *Drinking Water Standards* purposely are liberal, permitting 10 per cent or less of the 10 ml. tubes of a series of samples to be positive for coliform organisms. Obviously, the value of this test is reduced unless a number of representative samples are collected under known conditions so that laboratory data of statistical significance may be properly appraised in the light of field conditions. The presence of coliform organisms in a sample, therefore, should be considered as indicating a need for a search for their origin and significance, and not that the sample necessarily represents water of unsafe sanitary quality.

While the above basic attitude or policy is generally accepted, the subject is being reviewed at this time because it is evident that the present bacteriological techniques are not sufficiently exact to furnish sanitary engineers with a precise measure of sanitary quality. Engineers, however, will desire the continued refinement of bacteriological technique with the hope that a more precise test may be developed to disclose contamination of definite public health significance. High hopes have been raised in some quarters that the Eijkman test would fulfil this need, but this test so far has not been accepted as having sufficient specificity for this purpose.

On the other hand, progress in water treatment may outstrip progress in the development of more precise laboratory procedures for the bacteriological ex-

amination of water. For instance, experience with free residual chlorination discloses that with certain supplies all lactose-fermenting bacteria giving positive presumptive tests may be eliminated by this process. This suggests that the criterion of successful treatment is the absence of *positive presumptive tests* rather than the absence of *positive confirmed tests* for members of the coliform group. Therefore, under these specific circumstances a simple technique providing a broader measure of general bacterial pollution would be more applicable for practical purposes than refinement in bacteriological examination to secure greater specificity. The use of the presumptive test, however, would provide a more rigid standard of bacterial quality because of its greater scope, so a new set of guiding principles would have to be developed as to interpretation and application. While the simplicity and speed of the presumptive test may provide a useful means of controlling free residual chlorination, it is evident, however, that this test cannot be used in connection with raw waters which may be exposed to bacterial pollution of little or no sanitary significance, or in the appraisal of supplies which may be exposed to secondary pollution while the water flows through open equalizing reservoirs, etc. Therefore, it may be concluded that the present standard test for coliform organisms or the more inclusive presumptive test may be satisfactory for the control of treatment processes, but that a more specific test is needed for determining the sanitary quality of raw waters or the sanitary quality of water as delivered to the consumer.

Accordingly, this committee attempted to organize a program for the typing of coliform organisms which were present in treated supplies where knowledge as to sanitary conditions was well established, for the purpose of collecting

more extensive data upon the relative sanitary significance of various members of the coliform group. This investigation had to be restricted to studies in New York and Massachusetts because of war conditions. Final results are not available at this time.

Preliminary data from Massachusetts as to the typing of about 800 cultures disclose no trends which may be correlated with sanitary conditions.

The preliminary studies in New York State included the typing of coliform organisms isolated from several treated supplies. There was a sufficient number of positive tests to permit the collection of quantitative data for only one of these supplies. This supply serves one of the larger cities in the state and is secured from two large lakes which are free from appreciable pollution of human origin. Treatment by chlorination is effective, as disclosed by results of the examination of samples collected throughout the year at a point immediately after treatment. The chlorinated water so treated flows through two large equalizing reservoirs which, because of their size, are uncovered. The reservoirs are so constructed that surface drainage is not a problem and they are fenced and patrolled. Samples collected from the reservoirs and also from the distribution system are free from coliform organisms during the colder season of the year. There is progressive increase in the degree of pollution during the summer, and at times, 15 per cent of the 10 ml. portions of series of samples contained coliform organisms. The only known source of pollution is dust and the occasional presence of a few water fowl.

The following tabulation gives the results of the typing of the coliform organisms isolated from this supply of which 115 cultures were isolated. Ninety-three of the cultures have been typed so far. Fifty-seven, or 61 per cent, of these cultures belong to the

intermediate group according to the *Bergey's Manual*, whereas 10 cultures, or 11 per cent, belong to the coli section and 26 cultures, or 28 per cent, to the aerogenes section.

*Division of Laboratories & Research
New York State Department of Health*

Temporary Classification of Cultures

*(Classified in accordance with Bergey's
Manual—Fifth Edition, 1939—
Second Printing, 1940)*

Cultures isolated from portions of samples of a large public water supply, confirmed for presence of bacteria of the coliform group by techniques outlined in *Standard Methods for the Examination of Water and Sewage*.

Total number of cultures examined up to
October 15, 1946 = 115

Coli Section

Bact. coli = 10

Intermediate Section

Bact. coli var. *acidi lactici* = 2

Bact. coli var. *neapolitana* = 9

Bact. coli var. *comminior* = 4

Bact. freundii = 42

Aerogenes Section

Bact. aerogenes = 26

Not completed = 22

It is significant that the probable origin of the bacterial pollution of the water from the reservoirs of this supply cannot be inferred from the results of the typing of the coliform organisms found present. The relative proportion of the three subgroups may be of some significance, but there is no consistency in the available data which would permit the establishment of guiding principles.

Therefore, for the present, it would appear that coliform organisms as a group would have to be used in accordance with standard methods as indicator of bacterial pollution of water, with emphasis upon the need for a survey to permit one to appraise the sanitary significance of such pollution. It is

disconcerting, however, for sanitary engineers not interested in details of bacteriological technique to realize that no distinction is made by the standard technique or even by the usual typing tests between *Bact. coli* and, for instance, organisms associated with the rotting of vegetation; namely the *Erwiniae*. Therefore, as stated previously, there will be a continued demand for more precision as to the bacteriological examination of samples of potable water to meet the needs of those lacking specialized training required for discriminating appraisal of any sanitary significance of various members of the coliform group, or needed in appraising the results of the standard test for coliform organisms. The committee urges, therefore, that there be a more intensive typing of coliform organisms isolated from a variety of the supplies so as to accumulate quantitative data for a greater variety of supplies than are available at present. The continued study of a single-media test like the use of Lauryl Sulfate Tryptose Broth for the detection of coliform organisms, and of the more specific tests like the Eijkman test for *Bact. coli* also should be encouraged. The streptococcus test also might be reappraised as to its applicability.

DRINKING WATER STANDARDS

The acceptance by the Board of Directors of the American Water Works Association of the *Drinking Water Standards* as standards for all public water supplies in the United States and the Board's voluntary acceptance of the authority of the various state departments of health in matters relating to compliance with these *Standards* represents an important constructive step of great credit to the American Water Works Association, and of significance to public health. This official act has extended the significance and applicability of the standards from the legally

restricted field of water supplies serving common carriers, to public water supplies in general, and should result in a more uniform and improved practice. This expansion of the influence of the *Drinking Water Standards*, however, makes it essential for state departments of health as "reporting agencies" to exercise discretion and best technical judgment in the interpretation and enforcement of the *Drinking Water Standards*. The introduction to the *Standards* advocates this policy. In other words water supplies should be appraised by public health officials in the light of all factors affecting the sanitary quality of the water from the source of supply to the service pipe of the consumer, so that ample stress will be placed on equipment, supervision and maintenance, effectiveness of treatment and laboratory control, rather than the results of the bacteriological examination of the samples being over-stressed. The appraisal of water supplies in this broad manner requires the exercise of discriminating technical judgment in the evaluation of many intangible factors, such as reliability of supervision. This appraisal, however, should go still further when considering so-called "sanitary defects," which are so defined by the *Standards* as to include cross-connections, backflow connections, and faulty plumbing fixtures.

It is generally accepted that local water supply officials are responsible for the quality of water reaching the premises of the consumer. The revised *Drinking Water Standards* recognizes, however, that conditions on consumer premises are the responsibility of the consumer. Inasmuch as the interest of the consumer, that is, the public, is the quality of the water reaching the ultimate tap of the consumer and, as the consumer cannot be expected to purchase and maintain suitable plumbing fixtures, local health officials interested in the quality of the water actually

utilized by the consumer must exercise supervision through the enforcement of plumbing codes and by coöperating with municipal building departments when such matters are not handled by local health departments. It is fortunate, therefore, that the *Standard Plumbing Code*, now under development by the American Standards Association with the active assistance of the American Public Health Association and the American Society of Mechanical Engineers, is nearing completion and will be available on a national basis to those concerned with this important field.

OBSCURE WATER-BORNE DISEASES

As previously stated, there seems to be no evidence that unusual water-borne diseases have been imported into this country from the tropics by the returning armed forces. Infectious hepatitis has been reported to be water-borne in several instances. This disease recently was added to "reportable diseases" in New York State. Definite evidence as to whether or not water is the normal vector for the transmission of this virus disease has been lacking, so the discussion of the subject at this conference is welcome.

Poliomyelitis has been considered in this connection because the virus has been isolated from sewage. In this connection, it would seem pertinent to follow the attitude of Maxcy² as to the criteria for the water-borne transmission of disease. Briefly, they are as follows:

1. Those diseases which are associated with insanitary conditions
2. Which are reduced in incidence when water supply improvements are made
3. Which increase in incidence with epidemic rapidity when water supplies are subject to temporary pollution, or when treatment fails
4. Which have greater incidence among those using a suspected supply than among other groups using different supplies which are alike in all other pertinent respects

Maxcy concludes that evidence that poliomyelitis is water-borne is "conspicuous by its absence." In spite of this reassuring situation, it is gratifying to learn by recent work in Michigan,³ that the virus of poliomyelitis is nothing like as resistant to the action of chlorine as previously was thought to be the case, inasmuch as 0.2 p.p.m. free residual chlorine will destroy the virus in a matter of 10 minutes. This is another illustration of the value of free residual chlorination.

DISCUSSION

The discrepancy between the state of technical developments and the degree to which such developments have been applied focuses attention on the basic problem facing local water supply officials as well as health agencies interested in improving the quality of public water supplies. The basic problem is the allocation of adequate funds for the employment of properly trained personnel to operate satisfactory water works structures. Further technical advances and efforts of health departments will be of little avail unless there be concerted effort to improve the overall planning of water supply operation, including the important aspect of financing, especially in connection with small supplies.

The results of inspections and sampling of wells and springs serving rural property disclose in general that the majority of such sources of water supply yield water containing coliform organisms. In most instances this is because of poor construction of wells or springs which permit the entrance of incidental pollution rather than to pollution from permanent sources of human origin. On the other hand, many excellent bulletins are available describing the construction and proper location of wells and springs serving rural properties and for the disposal of excreta and sewage so as not to expose rural

water supplies to pollution. It is evident, therefore, that there is the same discrepancy between the state of technical knowledge and its application as with public water supplies.

A general appraisal of this situation would seem to indicate that little can be expected through the efforts of state departments of health until local health service is expanded to a point where sanitary inspectors are available for advice and assistance on a scale somewhat commensurate with conditions prevailing in urban communities. Such public health services would improve the supervision of small public water supplies serving limited population groups, such as real estate developments and small hamlets, summer resorts, etc. There seems to be a need, therefore, for the consideration of the administrative aspects of this situation to the end that the gap between established procedures and their application may be minimized.

CONCLUSIONS

A consideration of the many factors affecting the delivery of water of safe sanitary quality to the consumer stresses the need for the integration of the several fields of activity in a manner which would permit the development of a planned program within the financial resources at the disposal of local water supply officials and for careful utilization of existing structures and for future expansion so that undue stress will not be placed on any one phase of the problem. Generally speaking, however, experience has shown that intelligent and well trained personnel will do wonders with poor equipment, whereas modern equipment in the hands of shiftless or improperly trained personnel will soon deteriorate or give poor results.

Forty Years of the Russell Sage Foundation

On April 20, 1947, the Russell Sage Foundation celebrated its 40th anniversary with a brief historical statement of its activities issued by its general director, Shelby M. Harrison. It has spent more than \$21,000,000 "for the improvement of social and living conditions in the United States," \$12,000,000 in the Foundation's direct work and \$9,000,000 in grants to 119 different social agencies and special projects.

Among some of the Foundation's early and continuing activities is Forest Hills Garden (N. Y.), which was intended to demonstrate the values of careful land planning and architectural controls. It also originated the Regional Plan of New York. It has sold 5,200,000 copies of the educational measurements scales developed in its Department of Education. The Camp Fire Girls were organized by Dr. and Mrs. Luther Gulick while he was director of the Department of Child Hygiene. The Foundation helped finance the Pittsburgh Survey, after which it organized its own Department of Surveys and Exhibits, which has conducted surveys of social

conditions in many communities. Later in the anniversary year a two volume history will be published giving details on both grants and direct work.

Coincident with the anniversary report, announcement was made of the appointment of Donald Young as general director of the Foundation to succeed Shelby M. Harrison whose retirement, after 35 years of service, becomes effective on June 30, 1947. He has been general director for the last 16 years of that period.

The new general director, Mr. Young, comes directly from the Social Service Research Council where he has been executive director since 1945. He has been Professor of Sociology at the University of Pennsylvania, is a member of the American Academy of Political and Social Science, the Population Association of America, the Public Affairs Committee, and the American Statistical Association, among others, and author of a number of books and articles, among them *Minority Peoples in the Depression* and *Minority Peoples in a Nation at War*.

An Epidemic of an Acute Meningo-encephalitis in Giles County, Tennessee

An Unusual Disease

WALTER C. HUMBERT, M.D., C. B. TUCKER, M.D., F.A.P.H.A.,
K. T. MOSLEY, M.D., AND L. K. BISHOP, M.D.

*Tennessee Department of Public Health and the Department of Preventive
Medicine and Public Health, and Pediatrics, Vanderbilt University
School of Medicine, Nashville*

DURING the past few years an increase has been noted in the number of reported cases of virus infections in the United States. Poliomyelitis is one of those infections which have shown an increase, there being more cases reported and being more widespread in epidemic form in 1946 than in any recent previous year. Reports of respiratory infections of virus origin also appear to be on an increase. An outbreak of a very unusual infection, presumably due to a filterable virus, occurred in Giles County, Tennessee, and adjacent areas during the summer of 1946. It is the purpose of this report to give briefly a description of the clinical manifestations of the disease and the features of the epidemic.

During the second week of June, 1946, the physicians in Giles County reported to the local health officer the occurrence of an outbreak of an unusual disease. A clinical and epidemiological investigation was instituted immediately. During June and July, 209 cases were reported to the local health department. Sporadic cases have continued to occur up to the date of this report. Because of the failure of the families to seek medical attention due to the characteristics of the infection, it is estimated that there were two unre-

ported cases for every case reported. In addition, many cases occurred in counties adjacent to Giles County. An epidemiological and clinical history was obtained on 105 of the 209 reported cases. This report is based on these cases. It is interesting to note that no cases of acute anterior poliomyelitis were reported to the local health department during 1946 prior to the preparation of this report.

CLINICAL MANIFESTATIONS

Signs and Symptoms—The majority of the cases were characterized by sudden onset of fever, which usually was preceded by chilly sensations (Table 1). This was followed shortly by severe,

TABLE 1
Predominating Symptoms of Cases of an Epidemic of Meningo-encephalitis in Giles County, Tennessee, June, 1946

Symptoms	Number of Cases	Per Cent
Total	105
Headache	99	94.3
Fever	99	94.3
Nausea	81	77.1
Vomiting	79	75.2
Stiffness of Neck	64	61.0
Pain in Eyes	58	55.2
Photophobia	54	51.4
Pain in Extremities	38	36.2
Constipation	31	29.5
Pain in Abdomen	30	28.6
Sore Throat	28	26.7
Pain in Back	27	25.7
Chill	25	23.8
Diarrhea	4	3.8

unremitting headache, malaise, muscle aches, lumbar pain, and complaints of stiffness of the back and neck. In addition to these, there was one other outstanding complaint, retro-bulbar pain, which occasionally was associated with photophobia. The patients usually volunteered the information that motion of the eyeballs was exquisitely painful and that they preferred to lie in a darkened room with their eyes closed.

Soon after the onset of the above symptoms, marked nausea and vomiting followed which persisted for approximately 24 hours. This was associated with abdominal pain in the severe cases and occasionally with constipation. No significant diarrhea was noted. Despite the finding of vesicular pharyngitis in about 90 per cent of the cases, only 26 per cent of the cases complained of sore throat. These patients complained more of a dryness of the posterior pharynx than of true pain.

Neurological complaints were confined to hyperesthesias and paresthesias which were of only moderate intensity. No history of convulsions was obtained from any patient.

The picture found on physical examination was remarkably uniform. The general appearance of the patients was that of an acutely ill, irritable individual who obviously was quite uncomfortable, lying quietly in bed and extremely reluctant to move. Rarely was any significant degree of disorientation found. A mild generalized lymphadenopathy was found frequently. No skin lesions were observed.

Examination of the eyes revealed no significant conjunctivitis. Pupillary reactions were normal and no nystagmus was noted. Extreme retro-bulbar tenderness was demonstrated by either gentle pressure on the eyeballs or motion of the eyes. Fundiscopic examination was normal in all cases.

The ears, nose, and mouth were normal in all patients; however, a typical

vesicular pharyngitis was found in almost all the cases examined and in many of the familial contacts without other evidence of illness. The pharynx presented a mottled, edematous appearance with vesicles found chiefly in the tonsillar area, posterior pharyngeal wall, and occasionally on the uvula and soft palate. The individual vesicle was a superficial, small lesion from 0.5 to 1 millimeter in diameter, presenting a "dew-drop" appearance on the pharyngeal mucosa. In contradistinction to the lesions found in herpes simplex^{1, 2, 3} infections of the mouth, there was neither any involvement of the gums, buccal mucosa, or tongue, nor any tendency to ulceration. The pharyngitis was further distinguished from herpes by the absence of pain.

No significant abnormality was found on examination of the heart and lungs.

In the majority of cases the abdomen was somewhat distended. Mild abdominal tenderness was elicited in the severe cases only.

On neurological examination a positive Brudzinski reaction was obtained uniformly; however, the Kernig reaction was negative. Rather marked spasticity of the paravertebral muscles with inability to raise the head with the shoulders elevated, similar to that found in acute poliomyelitis, was present usually in the early stages of the disease. The deep tendon reflexes were equal and active, being slightly hyperactive at onset of the illness. The superficial reflexes were normally active with the exception of the abdominal reflexes. In cases with abdominal distention these latter reflexes were diminished or absent, though the cremasteric reflexes remained active. No other pathological reflexes were noted. Moderate transitory weakness of the left anterior tibialis muscle was demonstrated in only one case, a 19 year old white female. No other instances of muscle weakness were found nor did any cases of "lead-pipe"

rigidity of the extremities occur.

Course of the Disease—In children and in the majority of adults recovery was complete in 24 to 48 hours. In many of the adult cases, however, the illness continued from 5 to 10 days with high fever, severe headache, malaise, and with the other symptoms which have been related. Except for general weakness, all these cases recovered without ill effects. No deaths were reported.

Laboratory Findings—The hemoglobin and red blood cell counts were normal. A mild leukocytosis ranging from 8,000 to 13,000 was noted with differential counts showing a slight increase in lymphocytes—average 42 per cent of the total count; no increase in eosinophils was present. Urinalysis revealed nothing abnormal. Agglutination tests for *Proteus*, *Brucella*, typhoid, and paratyphoid were negative as were blood, nose, and throat cultures.

Three spinal fluid examinations were performed with the following results: (1) 170 white blood cells per cu. mm. of spinal fluid, negative Pandy test (quantitative sugar and protein determinations were not performed); (2) 42 white blood cells per cu. mm. of spinal fluid, negative Pandy test, and 56 mg. per cent total spinal fluid protein; (3) 8 white blood cells per cu. mm. of spinal fluid, negative Pandy test, and 47 mg. per cent total spinal fluid protein. The first two specimens were obtained from two patients on the 7th day of their illness and the other specimen was obtained on the 8th day of illness of a third patient. Quick-frozen spinal fluids were submitted to the National Institute of Health for cultures, which were negative.

Quick-frozen blood and fecal specimens also were submitted to the National Institute of Health for examination. These examinations have not been completed.

Nasopharyngeal washings were col-

lected early in the disease from 4 severe cases. These were quick-frozen and transported in dry ice and submitted to Dr. G. John Buddingh of the Department of Pathology, Vanderbilt University School of Medicine, for virus study.

Investigations undertaken with these nasopharyngeal washings are currently in progress and, as yet, are far from completion. Dr. Buddingh has given permission for the following tentative statements to be made in regard to his observations to date:

1. Bacterial studies did not seem to implicate any particular type or group of bacterial pathogens.

2. Inoculation of rabbit corneas with unfiltered washings failed to produce a keratitis which could be attributed to herpes simplex or other viruses known to be infective for this tissue.

3. Intraperitoneal and intracerebral inoculation of 4 to 6 weeks old mice with Berkefeld V filtrates of the washings failed to produce any recognizable pathological reaction or evidence of infection.

4. Inoculation of the chorio-allantois of 10 to 12 day old chick embryos with Berkefeld V filtrates of the nasopharyngeal washings produced a readily recognizable gross lesion within 48 hours. This membranal lesion has been reproduced constantly in serial passage without evidence of the presence of aerobic or anaerobic bacteria. Berkefeld V filtrates of suspensions of membranal lesions have the capacity for reproducing the lesion but indications are that much of the infectious agent is held back by the filter. Microscopic studies thus far of the membranal reaction have failed to reveal any specific characteristics. No inclusion bodies associated with many of the known viruses have been observed. It is felt that fairly good presumptive evidence has been obtained that a filter passing agent has been isolated but that its essential characteristics are as yet un-

known. That a virus differing from those which are now recognized has been isolated seems to be a distinct possibility.

Serological studies designed to demonstrate the development of specific neutralizing antibodies by comparative tests with acute and convalescent serum collected from several of the patients in this epidemic as yet are incomplete as are studies of the same type with serum from immunized laboratory animals.

FEATURES OF THE EPIDEMIC

The first case of the infection which occurred in Giles County, as far as could be ascertained, became ill on June 8, 1946, in the Milky Way Farms community. This community is located ten miles north of Pulaski, the county seat. Table 2 gives the dates of onset by

TABLE 2

Dates of Onset of Cases in an Epidemic of Meningo-encephalitis in Giles County, Tennessee, June, 1946

Week Ending	All Cases	Milky Way Community	Pigeon Roost Community	Pulaski and Surrounding Area
June 8	1	1		
15	23	19	1	3
22	36	14	8	14
29	38	5	16	16

weeks of the 96 cases which were reported and investigated during June, 1946. It may be noted that the outbreak was explosive in character. The outbreak at Milky Way preceded the outbreaks in the Pigeon Roost Creek community and in Pulaski by about one week. The Pigeon Roost Creek community is located on the highway between Pulaski and Milky Way, three miles north of Pulaski. It appears that the infection traveled rapidly along the route of travel from the Milky Way community to Pulaski, the shopping center for the county. In the Milky Way community the outbreak rapidly reached a peak and had subsided by the first week in July. From the records

of secondary cases, it is believed that the incubation period was usually 2 to 7 days.

A complete study including an investigation of all households and an enumeration of the population was made in the Milky Way community. Since attack rates could be calculated for this group, they were used as an example of the outbreak in the county. It was found that there were 137 persons living in the Milky Way community of whom 50 were white males, 38 white females, 30 colored males, and 19 colored females.

Table 3 gives the distribution of cases in the Milky Way community by age.

TABLE 3

Age Distribution of Cases in an Epidemic of Meningo-encephalitis in the Milky Way Community, Giles County, Tennessee, June, 1946

Age in Years	Population	Number of Cases	Rate per 100
Total	137	38	27.7
0- 9	33	13	39.4
10-19	36	12	33.3
20-29	15	4	26.7
30-39	27	6	22.2
40-49	12	2	16.7
50-59	9		
60 and over	5	1	20.0

It may be noted that the attack rate was 28 per 100 population in the community. The exceedingly high clinical attack rate, together with probable sub-clinical infections represented by the finding of vesicular pharyngitis among many familial contacts, is evidence of a virulent infection among a non-immune population. It appears from the attack rate in this community that the infection occurred somewhat more frequently among the younger age groups. It may be noted that the attack rate was 39 per 100 population in the age group 0-9 years, 33 per 100 population in the age group 10-19 years, 27 per 100 population in the age group 20-29 years, 22 per 100 population in the age group 30-39, and 11 per 100 population in the age group 40 years and over.

In Table 4 is given the race and sex distribution of cases in the Milky Way

TABLE 4

Sex and Race Distribution of Cases in an Epidemic of Meningo-encephalitis in the Milky Way Community, Giles County, Tennessee, June, 1946

Sex and Race	Population	Number of Cases	Rate per 100
Total	137	38	27.7
Total White	88	31	35.2
White Males	50	15	30.0
White Females	38	16	42.1
Total Colored	49	7	14.3
Colored Males	30	4	13.3
Colored Females	19	3	15.8

community. The attack rate among the white population was more than twice the rate among the colored population. The rate among the white population was 35 per 100 and among the colored population 14 per 100. This difference was noticed also in other sections of the county, particularly in Pulaski. The attack rate among males and females appears to have been about the same.

Table 5 gives the secondary attack rates of acute meningo-encephalitis among familial contacts in the Milky Way community. In computing the secondary attack rate, all persons who

TABLE 5

Secondary Attack Rates among Familial Contacts of Cases with an Acute Meningo-encephalitis in the Milky Way Community, Giles County, Tennessee, June, 1946

Age in Years	Population	Number of Secondary Cases	Attack Rate per 100
Total	73	19	26.0
0-4	12	4	33.3
5-9	2	1	50.0
10-14	9	2	22.2
15-19	8	1	12.5
20 and over	42	11	26.2

had onsets more than 24 hours after the initial case or cases were counted as secondary cases. It will be noted that the secondary attack rate in this community was 26 per 100 population compared to the general attack rate of 28 per 100 population. It would appear

that the chance of obtaining the infection in the general population was as great as among familial contacts, which indicates that the infection was widespread among this non-immune population.

An investigation was made of the possible mode of transmission of the infection. A sample of the Milky Way community water supply taken during the epidemic was negative for coli-aerogenes organisms. Also, a sample obtained from a spring used as a source of water by several families in this community was negative for these organisms. In the Pigeon Roost Creek area, the sources of water were numerous, including springs, wells, and cisterns. In Pulaski, which has an approved water supply, samples obtained during the epidemic were negative for coli-aerogenes. Since numerous sources of water were used, this vehicle can be ruled out as a possible mode of transmission.

In the Milky Way community there were two milk supplies. In the Pigeon Roost Creek community and in Pulaski numerous sources were present. In the former area, most families had their own cows as a source of milk. Under these circumstances it is very unlikely that milk was a mode of transmission of the infection.

An entomological investigation was made with particular reference to flies and mosquitoes. House flies were not numerous, although they were more numerous in the Milky Way community. No *Stomoxys calcitrans* were seen. In the Milky Way community *Anopheles punctipennis* and *Culex quinquefasciatus* were numerous in natural resting places. A few larvae of *Culex apicalis* were collected in a spring. In the Pigeon Roost Creek community numerous adults of *Anopheles punctipennis* were found in natural resting places such as under bridges, under rock ledges, and in spring houses. A few *Anopheles*

quadrinaculatus were found in one spring house. In the City of Pulaski, a few *Anopheles punctipennis*, *Culex apicalis*, and *Culex restuans* larvae were found in inverted automobile tops in a junk yard and a few larvae of *Culex quinquefasciatus* were taken in old tires. Only in the Milky Way community were mosquitoes sufficiently numerous to cause complaints from the inhabitants. No other known arthropod vectors were found to be present in unusual numbers. Inquiry was made in the Milky Way community in regard to illness among domestic animals. No illness among such animals had occurred in recent months.

No history of common meetings such as picnics, dinners, etc., could be obtained. No food used in common by all cases investigated could be incriminated.

The explosiveness of the outbreak, the rapid spread of the infection between the Milky Way community and other parts of the county, particularly in the City of Pulaski, the repeated finding of a history of contact with other cases, the onset of multiple cases in the families in 2 to 7 days after the onset of the initial case in the family, the multiplicity of subclinical cases manifested by asymptomatic vesicular pharyngitis, and the absence of any evidence of transmission of the infection by other means, suggest that in all probability this infection was transmitted through direct contact with clinical and subclinical cases of the disease.

SUMMARY

A brief clinical and epidemiological description of an epidemic of an unusual disease which occurred in Giles County, Tennessee, during June and July, 1946, has been given. The authors have not been able to find in the literature a description of an infection which is similar to that which occurred in this area. Unconfirmed reports of similar

outbreaks which occurred in Louisiana, Texas, and Richmond, Va., during the summer of 1946 have come to our attention since this investigation was made.

The epidemic was explosive in character, rapidly spreading from the Milky Way community to other parts of the county and adjacent areas. The disease occurred among both sexes with about the same frequency but somewhat more frequently among the younger age groups. The attack rate among the white population was more than twice that among the colored population. Multiple cases in households was the rule, with an incubation period usually of 2 to 7 days.

The disease was characterized by sudden onset, chilly sensations, fever, severe headache, retro-bulbar pain and tenderness, photophobia, muscular pains, constipation, drowsiness, irritability, stiffness of the back and neck, vesicular pharyngitis, hyperactive reflexes, increased protein and cellular elements in the spinal fluid, with the disease of longer duration in adults, and with recovery in 2 to 10 days, without sequelae. The short incubation period and duration, mildness of the infection, and the lack of sequelae, together with absence of the typical manifestations of other known encephalitides, as St. Louis and Western equine encephalitis, apparently indicate that this may represent a new disease entity.

The evidence thus far accumulated indicates that a filterable virus is the etiological agent of this disease.

ACKNOWLEDGMENT—The authors wish to acknowledge the assistance of the physicians in Giles County. Without their wholehearted cooperation this study would not have been possible.

HOMER FOLKS, STATESMAN EMERITUS

THE retirement on February 18 of Homer Folks as Secretary of the State Charities Aid Association of New York State marks the end of an epoch. When Mr. Folks resigned on his eightieth birthday, he had completed 54 years of service in this post, service which has been as notable in the field of public health as in that of public welfare.

After graduation from Albion College in 1889 and Harvard in 1890, Mr. Folks became General Superintendent of the Children's Aid Society of Pennsylvania, one of the first university men to take up social work as a career. From Philadelphia, he came in 1893 to take up the position which he has resigned this spring. Early in his study of the problems of New York State, he realized the important rôle of health as a primary factor in welfare. On Mr. Folks's recommendation in 1907, the State Charities Aid Association began a movement, with the State Health Department and other agencies, for the prevention of tuberculosis in the State of New York outside of New York City. He helped to direct the organization of what rapidly became, in the judgment of competent observers, the most comprehensive and successful state campaign in this country for preventing tuberculosis. It resulted in the enactment of a number of important statutes, the establishment of a series of county tuberculosis hospitals and clinics, and the employment of a large number of public health nurses. Since 1907, the tuberculosis death rate in up-state New York has declined from 152.8 per 100,000 population to 32.8 in 1945, a reduction of 78.5 per cent. Mr. Folks was chosen President of the National Tuberculosis Association in 1912.

In 1910, the S.C.A.A. Committee on the Care of the Insane began the promotion of activities for the prevention and early recognition and treatment of mental disorders. At this time (only two years after the mental hygiene movement was launched by Clifford Beers) the name of the committee was changed to the State Committee on Mental Hygiene and it has helped to secure many improvements in the state program for dealing with the insane, including the establishment of out-patient clinics and the employment of psychiatric social workers. Mr. Folks has long been a member of the National Committee for

Mental Hygiene, with which the Association's State and City Committees on Mental Hygiene are affiliated.

In 1913, having joined the American Public Health Association in 1912, Folks entered the wider field of health administration, as a member of a Special Public Health Commission to recommend a revision of the health laws of the state. With Herman M. Biggs as Chairman and Folks as Secretary, this commission prepared a new and far-sighted program which introduced the conception of the Commissioner-Council form of state health administration. This program, which was promptly put in force, placed New York at once in the forefront of public health progress, and has since been adopted by many other states. Folks has been a member and Vice-Chairman of the New York Public Health Council since its inception and he took a prominent part in the work of the more recent Special Public Health Commission in 1930.

Mr. Folks also contributed in important degree to the development of health programs in the field of child welfare, and was President of the American Association for the Study and Prevention of Infant Mortality in 1915.

During World War I, Mr. Folks went to France in June, 1917, and organized and directed the Department of Civil Affairs of the American Red Cross Commission to France. He developed bureaus dealing with tuberculosis, child welfare, cripples, relief in the war zone, and relief of refugees throughout France. At the end of the war, Mr. Folks, then a Lieutenant Colonel of the American Red Cross, made a survey of the civilian populations of Italy, Greece, Serbia, Belgium, and France to aid the American Red Cross in planning for post-war relief. In 1921 he made another trip to eastern Europe for the American Red Cross, as a special adviser in organizing its child health work.

Between 1923 and 1930, the S.C.A.A. was the representative of the Milbank Memorial Fund in the health demonstrations in Cattaraugus County and Syracuse, undertaken for the purpose of showing what benefits could be realized by a typical rural county and a medium sized city through a more comprehensive application of scientific knowledge as to the prevention of disease and the promotion of health. Mr. Folks took an active part in these demonstrations.

Under the leadership of the State Health Department, the Association in 1926 joined a coöperative effort for the control of diphtheria in up-state New York through promoting the immunization of young children against that disease. This resulted in a 98 per cent reduction in mortality and sickness. The Association also joined in 1932, at the request of the State Health Department, the campaign for the prevention and reduction of venereal disease and the promotion of social hygiene.

Governor Hughes once said that Homer Folks was the ablest politician of his acquaintance; and it is true that the chain of local tuberculosis associations and public health associations which he built up throughout New York State was a notable example of the fact that powerful pressure groups can function in the public interest as well as in the service of some private cabal seeking special advantage. He was much more than a politician, however. He was a statesman of the public good, a wise and judicious adviser, a tireless and inspiring leader. Few persons now living have made such outstanding contributions to the cause of public health in the United States.

BUILDING CODES AND HOUSING CODES: WHO SHOULD ENFORCE THEM

THE Building Code is a well established instrument of municipal administration. It is, as a rule, a bulky and detailed document, involving minute specifications which are sometimes out-of-date six months after they are written. Such codes generally include many provisions which make for exorbitant costs and invariably omit many conditions having a vital bearing on the health of future occupants. From the standpoint of structural safety and control of fire hazards, however, modern building codes offer ample safeguards. They are generally enforced by a building department or a tenement house department through approval of all plans for new construction, and inspection of the structures during erection.

The Housing Code, on the other hand, is a more nebulous conception. In some communities, Housing Codes have been formulated which deal with new construction as well as old and thus include a major part of the functions of the Building Code. To limit somewhat the area of chaos, we shall confine ourselves here to the consideration of those parts of a Housing Code which deal with conditions of actual occupancy. Most housing codes deal only with tenements or other multi-family structures. Housing codes that deal with all occupied dwelling units have rarely been adopted. In some cities there are no written provisions whatever and the health officer must deal with individual hazards as they come to light under the ordinary procedure for abating nuisances. A few cities, such as Baltimore and Milwaukee, have well drawn Housing Codes prepared and administered by the department of health. Sometimes, the same dwelling may be subject to inspection by representatives of the health department, the building department, the fire department, the police department and the tenement house department. In New York City, the Building Department conducts the only routine inspection with regard to occupancy conditions in tenements; and the Health Department responds only to specific nuisance complaints. Chicago has recently adopted a similar policy. Looking at the whole national situation, we see a picture best exemplified by the *New Yorker's* "Department of Utter Confusion."

This subject is discussed from the standpoint of the expert in administrative law by Charles S. Ascher in the present issue of this *Journal* and we commend his analysis to our readers.

It is a basic principle of sound administration that duplication of identical or related functions should be avoided because such duplication is wasteful of time and money and tends to confusion and lack of defined responsibility. It seems clear—as a matter of ordinary routine—that one city department and only one should be responsible for the health and safety of the inhabitants of a given occupied dwelling; and that, in practice, this ideal should be approached as closely as possible.

If such a premise be granted, it seems equally clear that the one inspector in question should be on the staff of the health department. The health officer, and he alone, has the fundamental duty of protecting the health of the individual. He alone must investigate complaints of nuisances and follow up the requests of nurses that serious hazards shall be eliminated. The most progressive health officials are recognizing that—in this field as in that of medicine—the work of the department should be preventive and not merely alleviative; and they are there-

fore undertaking routine inspections of housing conditions as they have long carried out routine inspections of food handling establishments. The health department inspector can deal with such problems as arise with regard to water supply, waste disposal, heating and sanitary facilities, occupancy and overcrowding far more intelligently than the building inspector; and he can call on the building or fire department inspector in any cases where occupancy has vitiated the safeguards established when the building was approved for construction.

A second vital reason why the health department is the one body which should carry the responsibility for occupied dwellings is that the health department alone has the prescriptive right to formulate general performance requirements instead of the rigid and minute legal specifications with which the Building Code must deal. It would seem eminently wise that—in framing such code regulations—it should consult with the building department, the fire department, the tenement house department, the police department and the zoning board; but the regulations as finally adopted should be in the broad and flexible form of the usual Sanitary Code and not involve the minute specifications of the traditional building Code.

We suggest that the Building Code for new construction may well be left as it is in the hands of the building department and its engineering specialists; but we believe that a Housing Code for occupied dwellings should be drawn up by the health department and enforced by the routine inspection service of that department, with such aid as necessary—both in drafting and enforcement—from allied departments of the city government.

The desirability of such a policy and the details of its application (including the subject matter of such a code) are now under consideration by the Association's Committee on the Hygiene of Housing; and it is hoped that a report on the subject may be available before the close of the current year.

THE KITCHEN GARBAGE GRINDER

THE pen of the Editor has long been itching to deal with the possible future of the kitchen garbage grinder; and has been restrained only by fear of the wrath of some of our engineering friends. Useful experience has been obtained in certain Army barracks¹; but war conditions have, of course, put a temporary stop to civilian developments. Now, however, the issue must again be faced; and a recent editorial in *Sewage Works Engineering* indicates that our inhibitions may after all have been unfounded.

Morris M. Cohn has this to say in the editorial in question²:

Several cities in the United States have recently been considering the economic and engineering desirability of disposing of all community garbage via the sanitary sewer system. And, thus, a new era is being born in the realm of municipal sanitation.

For the past decade, the use of home food-waste grinders has been growing gradually in some 300 municipalities, as homeowners and realty developers have purchased these household appliances and plumbed them into kitchen sink drain lines. While some 50,000 homes, representing about 200,000 persons, have eliminated garbage storage, the amount of wastes discharged to the sewer system in any one community has had no noticeable effect on the amount of wastes collected by surface methods or the character of sewage carried by the sewer system.

It is only a matter of time until some community undertakes a program of completely eliminating garbage collections and substituting disposal of ground wastes into the sanitary sewer system. Left to develop without municipal intercession, the home grinding process

will develop slowly and it will be a generation, more or less, before a major percentage of homes will use the sewer as the means of transporting their food remnants. But, if a community makes home grinding a city-sponsored project, the conversion from surface collection to underground collection and disposal may occur within a few years.

As Cohn points out, there are, of course, two aspects to such a procedure as that proposed, assuming—as we may assume in the present case—that the devices available will actually perform their task. We must ask ourselves, “What will the process accomplish for the public health?” and, “What will it cost?”

Taking up the second of these questions first, there can be no categorical or general answer. The cost of the kitchen grinding unit is at present high; but its capital cost and maintenance must be balanced against the cost of collection of garbage and its transportation to a point of final disposal. The device will involve a definite increase in domestic water consumption; and addition of ground garbage to sewage will increase the cost of disposal of the sewage since both solid content and B.O.D. will be materially increased; but this must be weighed against the cost of garbage disposal in a given locality. Taylor³ has discussed the influences of the addition of ground garbage upon sludge storage capacity, sludge drying beds, and aerating. Tolman⁴ reviews the experience of two cities which have used the procedure and concludes that one ton of garbage per one million gallons of sewage will increase B.O.D. by only 10 per cent and that sludge from sewage to which ground garbage has been added settles better than normal sewage and can be effectively digested. He estimates the additional cost of sewage treatment due to addition of ground garbage at 40 cents per ton. Both this figure and the estimate of a 10 per cent increase in B.O.D. seem extremely low.

The balance of possible economies involved must be worked out by engineers in the light of local conditions. From the standpoint of the sanitarian, there are great advantages in what Tolman calls “Dual Disposal”—even if the cost is the same or slightly greater. The storage of garbage in the vicinity of the dwelling, its transportation through the streets, and its ultimate disposal, all involve sanitary problems which can be overcome only by meticulous care at all stages of the process. The garbage pail in the kitchen, the garbage can outside the back door, the garbage truck and the dump or hog farm or garbage disposal plant are all potential sources of offensive sights and smells. If not very carefully controlled (and rare is the community where such control exists), they may breed insects and attract and foster rats and other vermin. Disposal by hog feeding may involve serious dangers of trichinosis, as it is practised in many cities.

The domestic privy was once an essential feature even of city life. It is now, in urban communities, an anachronism. We suspect that the garbage can will ultimately follow the privy along the same road.

RESTAURANT SANITATION GOES SCIENTIFIC

IT is always exciting when science steps down from her academic heights to illumine the processes of daily living. A peculiarly neat and satisfying example

of this process is offered in a contribution by Mallmann and his associates published in the April issue of this *Journal*.¹

In the past, our standards for the humble—but essential—task of dishwashing have been vague and confused. They are commonly based upon “immersion at least 2 minutes in clear hot water at a temperature of at least 170° F. or ½ minute in boiling water” for hand-washed dishes; but it has been recognized that, with the use of dishwashing machines, variations in general and local temperatures, in mechanical removal of dirt and in detergent effects complicate the simple standard quoted above.

Mallmann, DeKoning, and Zaikowski have developed a procedure for the accurate measurement and standardization of the actual efficiency of dishwashing procedures of any kind, which involves two distinct approaches. The Michigan investigators first devised a standard “soil,” as they call it, in the form of a mixture of water, corn-starch flour, India ink, and test bacteria which can be evenly sprayed on china dinner plates, and dried upon them so as to produce a uniform material somewhat like that resulting from the soiling of eating utensils. The test organism selected was a chromogenic coccus, *Micrococcus caseolyticus*, chosen because of the ease of recognizing its colonies on plates and its high resistance to the preliminary drying process involved. This organism is slightly more resistant to heat than *Escherichia coli* and has about the same resistance as *Streptococcus fecalis*. The “soil” is of such a nature that it is not removed by ordinary rinsing processes but can be resuspended in sterile saline solution, so that plating before and after dishwashing will give an accurate determination of the per cent reduction due to a given heat treatment.

Even more striking and ingenious than this bacteriological measuring stick, is the device worked out for direct ocular demonstration of the effectiveness of a given form of dishwasher with regard to physical removal of foreign material. Here, the investigators have prepared another type of “soil,” containing fatty materials, eggwhite, milk, etc., simulating more closely the material found on used utensils and dried on the plates under standard conditions. To observe the actual performance of a given washer, plates of this type are placed in the washer and treated according to specifications and the amount of “soil” removed in washing determined by a delicate optical instrument which records the light reflected from the plate, the greater the light reflected, the more complete being the removal of the “soil.” This device can be taken by the inspector into the field, previously-prepared “soil plates” run through the washer, and a permanent visual record obtained which is far more convincing than a statement of percentage reduction of bacteria. The facts revealed by this technique have been startling and have called attention to the fact that general water temperature alone is a very inadequate measure of actual efficiency. The interference with cleansing action, due to faulty design which interferes with the cleansing effect of local currents, is most revealing. In certain supposedly good machines, the test plate is streaked like a zebra with unremoved “soil” where bars in the apparatus protect the plate from water flow; and the demonstration of these facts is leading to radical reforms in the design of the machines. All in all, this is a remarkable demonstration of the application of refined scientific procedure to one of the most important practical tasks of sanitation.

Clearing House on Public Health Salary Information

The Committee on Professional Education and the Executive Board, no less than the members of the Association, have been deeply concerned with the need for adjusting salaries of public health workers to 1947 conditions. The vexing problem has been to assemble the mounting evidence of inadequate compensation and its disastrous effects into meaningful and compelling form for administrators and those to whom they must look for increased appropriations. Data about present salaries are not lacking, but they are a long way from being inclusive and conclusive. There are great gaps in the information available. Titles of positions and job descriptions are varied between one state and another to a degree that makes comparison really difficult. An exhaustive salary study seemed at first to be the only solution, but on closer examination it is obvious that, while it might improve our semantics, it could only lead to what is already common knowledge—that in many parts of the United States public health workers are now being paid sub-subsistence wages by

1947 standards; nowhere, by the same standards, are they being paid liberally; and in only a handful of individual cases are they being paid “adequately.”

Pending the availability of some full-scale salary study, the *Journal* will bring to its readers facts, information, and comment that reach it through correspondence, conversations in the field and in the central office, and experiences with our Vocational Counselling and Placement Service, and it invites readers to take part in the discussion.

Professor Winslow led off with an editorial in the April *Journal* entitled “Are our Public Health Defenses Crumbling?” He called attention to the failure of the present financial rewards in public health to hold desperately needed workers in their jobs. We follow it up with a digest of “bid and asked” prices for public health services, as we know them, in the spring months of 1947. What comes next depends upon the response from the readers and upon our success in relating bits and pieces of information from here and there to our common problem.

Prevailing Rates of Compensation for Public Health Personnel Employed in 1947

Public health salaries have been adjusted to the rising cost of living only to a limited extent. The record shows that in many instances clerical and stenographic personnel employed by health agencies have received proportionately more liberal increases than professional persons who have been on the whole less vocal about their needs. It is apparent however that, whether

vocal or not, professional persons in public health are being drawn away from career employment in this field to take positions for which they are fitted as doctors, as engineers, as nurses, or as teachers, where the compensation level is more satisfactory than in public health. It is common knowledge that doctors and engineers often double or treble their incomes by moving from

public employment into private practice.

There were 306 public health and sanitary engineers employed by local departments of health in 1942. During the pressures of the war years perhaps a third of these persons were engaged in some form of direct war service with the Armed Forces. It is highly doubtful whether a census at the present time would show that more than 250 of this number are now in their former positions. Yet even in 1942 it was manifest that there was a clear deficit of a thousand engineers if local health departments are to be raised to even a minimum level of satisfactory performance. The newly trained engineers who are graduating from our universities find attractive positions in private employment. It may be necessary to raise current salary levels in many instances by as much as 40 or 50 per cent if we are to retain the present well experienced persons and recruit promising new personnel.

The Association offers for the information of health officers and other employers the following summary based on recent placement of a substantial number of candidates through the Vocational Counseling and Placement Service jointly operated by the American Public Health Association and the United States Public Health Service, with headquarters in the Association offices.

MEDICAL OFFICERS

An analysis was recently made of 48 physician candidates and 356 medical administrative or clinical openings in the Continental United States about which full information was available. Only seven of the candidates were willing to accept less than \$5,000 as a starting salary; 29 asked a minimum of at least \$6,000, and 7 asked \$7,000 or more. On the other hand, of the 356 openings more than half (210) paid a

starting salary of less than \$5,000 and only 63, or about one-sixth, paid as much as \$6,000. More than three-fourths were listed as starting below \$5,500. In terms of averages, the minimum acceptable to candidates was \$5,860, the average beginning salary for positions offered was \$4,900.

It is thus obvious that a physician with an M.P.H. degree plus field experience of at least six months can easily demand \$6,000 as a minimum entering salary. Men and women of the best quality personality have no difficulty in finding positions at \$6,500, \$7,000, and \$7,500 levels.

Even physicians without an M.P.H. but with good training and experience in some clinical specialty like tuberculosis, venereal disease, or maternal and child health are finding many openings at \$6,000, \$6,500, or \$7,000.

It is fruitless to advertise nationally medical positions at levels under \$6,000, except in circumstances under which a candidate will be provided with a stipend for training in a school of public health or other special advantages.

Even at these higher levels well qualified physicians are often receiving not more than half what they might earn on a net basis in clinical practice outside of public health. There is therefore little present incentive for the better kind of young men and women with medical degrees to go on for graduate work in public health, save for those few with a missionary zeal to whom income is a minor consideration.

SANITARY ENGINEERS

An analysis of 62 openings and 29 applicants for sanitary engineering positions reveals similar gaps between starting salaries offered and minima demanded by applicants. This is true in spite of the fact that the number of openings listed was only double the number of applicants, in contrast to

only one physician registered for every ten openings listed. Of the 62 positions listed, the beginning salary for 44, or nearly three-quarters, was less than \$3,600. Only 7 of the 29 candidates, on the other hand, were willing to start at salaries below \$3,600. One-half of the candidates asked for beginning salaries of \$4,000 or more; only 7 of the 62 openings were listed with starting salaries of \$4,000 or more. The average starting salary for the 62 openings was \$3,125, and the average minimum salary demanded by the 29 candidates was \$3,800.

STATISTICIANS

For a small group of both openings and applicants for statistical positions information was available showing the same relative spread between salaries offered and salaries demanded. Of 29 statistical openings listed, one-third offered less than \$2,600 as a starting salary; two-thirds less than \$3,600; and only three were above the \$4,000 level. Of ten applicants, on the other hand, five asked \$4,500 or more as a minimum and none was willing to accept less than \$3,000. In terms of averages, the minimum starting salary was \$3,220; the minimum figure applicants were willing to accept was \$4,090, or about one-fourth more.

OTHER GROUPS

Data for other groups of public health workers show the same trend but are not summarized here. The position

diversity among health educators and in laboratory personnel, for example, makes comparisons in these categories less valid than in those discussed above. However, a small group of openings for dentists and dentist applicants shows the same trend. Seven applicants asked a minimum starting salary of \$4,470, nine positions listed offered an average minimum of \$3,940. Only one applicant was willing to start at less than \$4,000; four of the openings listed were at this figure. No opening listed had a maximum figure of \$6,000; one applicant asked this figure as a starting salary; two others with a lower minimum hoped to secure \$6,000 openings. In interpreting these figures it must be remembered that for many reasons the needs of the employing agencies are not always matched by the applicant's desires or abilities, and *vice versa*.

Experience indicates the need for a concerted attack on low salaries in public health. The energy that is spent on raising salary standards now will do more to raise the standard of public health service than anything else that can be done. Indeed, unless efforts to raise salary standards parallel those to raise qualification standards, the latter effort will be largely nullified. That has been amply proved by the public school teacher crisis, as a result of which teachers with substandard certificates have multiplied rapidly in spite of rising standards of certification.

THE ASSOCIATION COMMITTEE LISTS

These pages again bring to the readers the lists of Association officers and Committee members. Once again they make a goodly company representing altogether more than 150 committees and other councils, a capable and loyal group of workers.

A certain proportion of the names of those formerly carried on such lists do not appear here. They have the Association's thanks for work well done in other years and for the fine spirit in which they have recognized the fact that, for the sake of the Association and its future effectiveness, leadership must be shared and leaders constantly developed through the assumption of responsibility. Our Association is stronger today because leaders

periodically have stepped aside in order that others may step forward to acquire such knowledge as they themselves have gained.

Change in leadership is becoming an accepted policy in the Association. Such a professional society is never strong if an informed few lead many uninformed though loyal followers. A strong association is composed of leaders many of whom could at any time take their turn and lead.

As we gratefully acknowledge the debt to those who have rendered their service as they carried their responsibilities of office, we turn with hope and expectation of other achievements to the men and women who are now to lead.

E. A. Reinke

Subcommittee on Field Training of Public Health Personnel

Gaylord W. Anderson, M.D., *Chairman*,
University of Minnesota, Minneapolis,
Minn.
Benjamin G. Horning, M.D.
Edward G. McGavran, M.D.
Pearl McIver, R.N.
Roy J. Morton
Wilson G. Smillie, M.D.

Consultants:

Edward S. Godfrey, Jr., M.D.
John E. Gordon, M.D.

Subcommittee on Personnel Administration

L. E. Burney, M.D., *Chairman*, State Board
of Health, Indianapolis, Ind.
(Personnel to be appointed)

Subcommittee on Salary Study

William R. Willard, M.D., *Chairman*, Yale
University, New Haven, Conn.
Richard F. Boyd, M.D.
Harold F. Dorn
M. R. Kinde, M.D.
M. Allen Pond
Wilson T. Sowder, M.D.
Ernest L. Stebbins, M.D.
V. A. Van Valkenburgh, M.D.
Alberta B. Wilson, R.N.

Committee on Research and Standards

Thomas Francis, Jr., M.D., *Chairman*, University of Michigan, Ann Arbor, Mich.

Reginald M. Atwater, M.D., *Secretary*, 1790 Broadway, New York, N. Y.

J. J. Bloomfield (1947)

Alfred G. Burgdorf, M.D. (1949)

Halbert L. Dunn, M.D. (1948)

Haven Emerson, M.D. (1947)

Gordon M. Fair (1948)

W. W. Frye, M.D. (1948)

James Gibbard (1949)

Wilton L. Halverson, M.D., *Chairman*, Committee on Administrative Practice (*ex officio*)

Friend Lee Mickle, Sc.D. (1949)

John F. Norton, Ph.D. (1949)

Elliott S. Robinson, M.D. (1947)

Thomas F. Sellers, M.D. (1947)

Fred W. Tanner, Ph.D. (1947)

Walter D. Tiedeman (1948)

Consultant:

Abel Wolman, Dr.Eng.

Subcommittee on Autopsies

Haven Emerson, M.D., *Chairman*, 600 West 168th Street, New York, N. Y.

George C. Dunham, M.D.

W. Thurber Fales, Sc.D.

Harrison S. Martland, M.D.

Paul D. Rosahn, M.D.

Milton C. Winternitz, M.D.

Subcommittee on Communicable Disease Control

Haven Emerson, M.D., *Chairman*, 600 West 168th Street, New York, N. Y.

Gaylord W. Anderson, M.D.

Captain T. J. Carter, M.C., USN

L. T. Coggeshall, M.D.

James A. Doull, M.D.

John E. Gordon, M.D.

James P. Leake, M.D.

Kenneth F. Maxcy, M.D.

Alton S. Pope, M.D.

George H. Ramsey, M.D.

Ernest L. Stebbins, M.D.

Subcommittee for the Evaluation of Methods to Control Air-borne Infections

James E. Perkins, M.D., *Chairman*, State Department of Health, Albany, N. Y.

F. W. Gilcreas

Alexander Hollaender, Ph.D.

Alexander D. Langmuir, M.D., *Secretary*

O. H. Robertson, M.D.

William F. Wells

George M. Wheatley, M.D.

C. P. Yaglou

Subcommittee on Food Utensil Sanitation

Walter D. Tiedeman, M.C.E., *Chairman*, State Department of Health, Albany, N. Y.

A. W. Fuchs, C.E.

N. O. Gunderson, M.D.

George J. Hucker, Ph.D.

Walter L. Mallmann, Ph.D.

Subcommittee on the Hygiene of Housing

C.-E. A. Winslow, Dr.P.H., *Chairman*, 333 Cedar Street, New Haven, Conn.

Frederick J. Adams

Charles S. Ascher

Rollo H. Britten

F. Stuart Chapin, Ph.D.

Henry S. Churchill

Robert L. Davison

Clarence W. Farrier

Alfred H. Fletcher

L. M. Graves, M.D.

E. R. Krumbiegel, M.D.

Bleecker Marquette

Robert B. Mitchell

M. Allen Pond

F. Carlyle Roberts, Jr.

Mary Rokahr

Abner D. Silverman

Donald Y. Solandt, M.D.

Howard P. Vermilya

H. A. Whittaker

Huntington Williams, M.D.

Sidney J. Williams

Coleman Woodbury

Henry Wright

Staff: 310 Cedar Street, New Haven, Conn.

Allan A. Twichell, *Technical Secretary*

Anatole A. Solow, *Research Associate*

Ann S. Copperman, *Research Associate*

Emil A. Tiboni, *Field Secretary*

Rose Olanik, *Assistant Secretary*

Subcommittee on Administration of Housing Regulations

Charles S. Ascher, *Chairman*, 2 Park Avenue, New York, N. Y.

Subcommittee on Research

M. Allen Pond, *Chairman*, 310 Cedar Street, New Haven, Conn.

Subcommittee on Standards for Construction and Fundamental Equipment

Henry S. Churchill, *Chairman*, 56 West 45th Street, New York, N. Y.

Subcommittee on Standards for Installed Household Equipment

Mary Rokahr, *Chairman*, U. S. Department of Agriculture, Washington, D. C.

Subcommittee on Standards for Space Design and Occupancy

Abner D. Silverman, *Chairman*, Federal Public Housing Authority, Washington, D. C.

Subcommittee on Substance of Housing Regulations

E. R. Krumbiegel, M.D., *Chairman*, Department of Health, Milwaukee, Wis.

Subcommittee on Morbidity Registration and Statistics

Lowell J. Reed, Ph.D., *Chairman*, The Johns Hopkins University, Baltimore, Md.

Gaylord W. Anderson, M.D.

Edwin L. Crosby, M.D.

W. Thurber Fales, Sc.D.

James P. Leake, M.D.

Franklin H. Top, M.D.

Ellen B. Whiteman

Association Committees

Committee on Constitution and By-Laws

Edward S. Godfrey, Jr., M.D., *Chairman*, State Department of Health, Albany, N. Y.

Haven Emerson, M.D.

Franklin M. Foote, M.D.

Charles E. Shepard, M.D.

Lasker Awards Committee

George Bachr, M.D., *Chairman*, One East 100th Street, New York, N. Y.

Francis G. Blake, M.D.

R. E. Dyer, M.D.

Thomas Francis, Jr., M.D.

Charles G. King, Ph.D.

Hugh R. Leavell, M.D.

Robert F. Loeb, M.D.

Karl F. Meyer, Ph.D.

James S. Simmons, M.D.

Ernest L. Stebbins, M.D.

Abel Wolman, Dr.Eng.

Editorial Board

Reginald M. Atwater, M.D., *Chairman*, 1790 Broadway, New York, N. Y.

Leona Baumgartner, M.D.

Martin Frobisher, Jr., D.Sc.

John M. Henderson

Ralph S. Muckenfuss, M.D.

Stuart Mudd, M.D.

Raymond S. Patterson, Ph.D.

C.-E. A. Winslow, Dr.P.H.

Nominating Committee for Governing Council Members

Earle G. Brown, M.D., *Chairman*, Nassau County Dept. of Health, Mineola, N. Y.

Lloyd M. Graves, M.D., Health Officers Section

Myrtle Greenfield, Laboratory Section

Hugo Muench, M.D., Vital Statistics Section

Arthur E. Gorman, Engineering Section

C. O. Sappington, M.D., Industrial Hygiene Section

Marietta Eichelberger, Ph.D., Food and Nutrition Section

John M. Saunders, M.D., Maternal and Child Health Section

Howard W. Lundy, Dr.P.H., Public Health Education Section

Pearl McIver, R.N., Public Health Nursing Section

Alexander G. Gilliam, M.D., Epidemiology Section

David Van der Slice, M.D., School Health Section

Frank C. Cady, D.D.S., Dental Health Section

Joint Committee on Housing and Health (Joint with the National Association of Housing Officials)

Bleecker Marquette, *Chairman*, 312 West 9th Street, Cincinnati, Ohio

A.P.H.A.

Rollo H. Britten

Alfred H. Burgdorf, M.D.

C. V. Craster, M.D.

L. M. Graves, M.D.

Alfred H. Fletcher

B. M. Pettit

Program Committee

Reginald M. Atwater, M.D., *Chairman*,
1790 Broadway, New York, N. Y.
Carl E. Buck, Dr.P.H.
Clara E. Councell
Geoffrey Edsall, M.D.
Franklin M. Foote, M.D.
Lester A. Gerlach, D.D.S.
Reba F. Harris
Theodore G. Klumpp, M.D.
S. S. Lifson
J. Lynn Mahaffey, M.D.
Joseph G. Molner, M.D.
Richard T. Page
Rosalie I. Peterson, R.N.
George O. Pierce
David E. Price, M.D.
Samuel L. Salasin, M.D.
Alice H. Smith
Franklin H. Top, M.D.
V. A. Van Volkenburgh, M.D.
Myron E. Wegman, M.D.
C.-E. A. Winslow, Dr.P.H.

Scientific Exhibits Committee

Franklin M. Foote, M.D., *Chairman*, 1790
Broadway, New York, N. Y.
Paul H. Brown, M.D.
Homer N. Calver
Vivian Drenckhahn
Francis B. Elder
Horace Hughes
S. S. Lifson
Willimina R. Walsh

Sedgwick Memorial Medal Committee

James S. Simmons, M.D., *Chairman*, Har-
vard University, Boston, Mass.
Thomas Francis, Jr., M.D.
Wilton L. Halverson, M.D.
Karl F. Meyer, M.D.
Harry S. Mustard, M.D.
William P. Shepard, M.D.
Abel Wolman, Dr.Eng.

Section Committees

Dental Health Section

Membership Committee

Olin E. Hoffman, D.D.S., *Chairman*, 1103
Hull Avenue, Des Moines, Iowa
M. A. Bailey
Lester A. Gerlach, D.D.S.
N. F. Gerrie, D.D.S.
Muriel K. G. Robinson, D.D.S.

Nominating Committee

F. C. Cady, D.D.S., *Chairman*, U. S. Public
Health Service, New York, N. Y.
K. A. Easlick, D.D.S.
J. M. Wisan, D.D.S.

Publications Committee

George A. Nevitt, D.D.S., *Chairman*, U. S.
Public Health Service, Washington, D. C.
Thomas W. Clune, D.M.D.
K. A. Easlick, D.D.S.

Resolutions Committee

R. C. Leonard, D.D.S., *Chairman*, State
Department of Health, Baltimore, Md.
W. H. Rumbel, D.D.S.
C. R. Taylor, D.D.S.

Engineering Section

Advisory Policy Committee to the Section Council

(Chairman and personnel to be appointed)

Committee on Air Pollution

H. A. Whittaker, *Chairman*, University of
Minnesota School of Public Health,
Minneapolis, Minn.
John Buxell
Gordon M. Fair
Burgess H. Jennings
Sol Pincus, C.E.

Advisers:**Epidemiology Section**

Alexander D. Langmuir, M.D.

Industrial Hygiene Section

C. P. Yaglou

Laboratory Section

Stuart Mudd, M.D.

Committee on Bathing Places (Joint with
the Conference of State Sanitary En-
gineers)

Warren J. Scott, *Chairman*, State Department of Health, Hartford, Conn.
Thomas M. Riddick

(Two additional appointments to be made)

Advisers:

Epidemiology Section

Ralph E. Wheeler, M.D.

Laboratory Section

Walter L. Mallmann, Ph.D.

Committee on Coördination of Public Health Engineering Activities

Roy J. Morton, *Chairman*, Vanderbilt University, Nashville, Tenn.

Gordon M. Fair

Alfred H. Fletcher

H. A. Kroeze

W. H. Larkin, C.E.

Charles L. Senn

Ellis S. Tisdale

Committee on Exploration of Research Needs

Blucher A. Poole, *Chairman*, 2715 Ryan Drive, Indianapolis, Ind.

V. M. Ehlers

Francis B. Elder

Harold B. Gotaas

Sol Pincus, C.E.

Committee on Industrial Sanitation

Herbert M. Bosch, *Chairman*, State Department of Health, Minneapolis, Minn.

Paul Houser

Blucher A. Poole

Adviser:

Industrial Hygiene Section

(To be appointed)

Committee on Municipal Public Health Engineering

J. Lloyd Barron, C.E., *Chairman*, National Biscuit Company, New York, N. Y.

Leonard M. Board

William J. Dixon

Morton S. Hilbert

Henry D. Peters

Charles L. Senn

Wilmer H. Schulze

J. A. Willman

Committee on Rural Sewage Disposal

William T. Ingram, *Chairman*, 1790 Broadway, New York, N. Y.

Paul D. Haney

Albert I. Howd

H. A. Kroeze

David B. Lee

Kenneth H. Spies

Samuel R. Weibel

Committee on School Sanitation

Herbert J. Dunsmore, *Chairman*, Calhoun County Health Department, Battle Creek, Mich.

Richard G. Bond

L. M. Clarkson

Albert W. Happy, Jr.

Samuel P. Kingston

Edwin L. Ruppert

Advisers:

School Health Section

Warren H. Southworth, Dr.P.H.

Public Health Education Section

(To be appointed)

Committee on Sewage Disposal

Langdon Pearce, *Chairman*, 910 South Michigan Avenue, Chicago, Ill.

Don E. Bloodgood, C.E.

Almon L. Fales

C. G. Gillespie

Clarence E. Keefer

Theodore J. Lafreniere

Maurice LeBosquet, Jr.

Floyd W. Mohlman, Ph.D.

Willem Rudolfs, Ph.D.

Francis M. Veatch

P. J. Alwin Zeller

Committee on Shellfish

Milton H. Bidwell, *Chairman*, State Conservation Department, Freeport, N. Y.

L. N. Clarkson

L. M. Fisher

Joseph B. Glancy

Richard Messer

John H. O'Neill

Sol Pincus, C.E.

Kenneth H. Spies

Edward Wright

Adviser:

Laboratory Section

Chester T. Butterfield

Committee on Water Supply

Charles R. Cox, *Chairman*, State Department of Health, Albany, N. Y.
James Bernard Baty, Major, U. S. Army
H. J. Darcey

Raymond J. Faust
Arthur E. Gorman
Raymond F. Goudey
Harold Stephens Hutton
Arthur D. Weston

Epidemiology Section**Committee on Bathing Places (to cooperate with the Committee on Bathing Places of the Engineering Section)**

Ralph E. Wheeler, M.D., *Adviser*

Committee on Air Pollution (to cooperate with the Committee on Air Pollution of the Engineering Section)

Alexander Langmuir, M.D., *Adviser*

Food and Nutrition Section**Joint Committee on Analyzing Frozen Desserts**

Frederick W. Fabian, Ph.D., *Chairman*, Michigan State College, East Lansing, Mich.
J. H. Shrader, Ph.D.
K. G. Weckel, Ph.D.

Oscar Boisvert
J. O. Clarke
Marietta Eichelberger, Ph.D.
Earl A. Louder, Ph.D.
Ethel A. Martin
William B. Palmer
Lloyd K. Riggs, Ph.D.
Paul F. Sharp, Ph.D.
Paul H. Tracy, Ph.D.

Committee on Assay of Foods

Henry T. Scott, Ph.D., *Chairman*, Wisconsin Alumni Research Foundation, Madison, Wis.
Fuller D. Baird
Esther L. Batchelder, Ph.D.
Ernestine Becker
Paul L. Day, Ph.D.
Conrad Elvehjem, Ph.D.
Herbert E. Longenecker, Ph.D.
Elmer M. Nelson, Ph.D.

Committee on Nutritional Problems

Helen S. Mitchell, Ph.D., *Chairman*, 699 Forest Road, New Haven, Conn.
Ruth C. Clouse, Ph.D.
Robert S. Harris, Ph.D.
Helen A. Hunscher, Ph.D.
Norman Jolliffe, M.D.
Charles G. King, Ph.D.
Frederic W. Nordsiek
William H. Sebrell, Jr., M.D.

Committee on Foods (Except Milk)

Harry W. von Loesecke, *Chairman*, U. S. Department of Agriculture, Washington, D. C.
Frank L. Gunderson, Ph.D.
George J. Hucker, Ph.D.
D. Breese Jones, Ph.D.
Harry D. Kruse, M.D.
Reginald C. Sherwood, Ph.D.
Roe E. Remington, Ph.D.

Committee on Remuneration

Margaret C. Moore, *Chairman*, State Board of Health, New Orleans, La.
Martha Koehne, Ph.D.
Ferdinand A. Korff
Ira A. Manville, M.D.
William A. Queen
Fred W. Tanner, Ph.D.

Committee on Membership and Fellowship

Alice H. Smith, *Chairman*, State Department of Health, Lansing, Mich.
J. Russell Esty, Ph.D.
Bernice Hopper
Ruth M. Kahn
Dan Mahoney
Donald K. Tressler, Ph.D.

Committee on Standard Methods for the Microbiological Examination of Foods

Harry E. Goresline, Ph.D., *Chairman*, U. S. Department of Agriculture, Washington, D. C.
M. Thomas Bartram, Ph.D.
James A. Berry
Edwin J. Cameron, Ph.D.
John L. Etchells, Ph.D.
Frederick W. Fabian, Ph.D., *Consultant*
Matthew E. Highlands

Committee on Milk and Dairy Products

Ethel A. Martin, *Chairman*, 111 N. Canal Street, Chicago, Ill.

Albert C. Hunter, Ph.D.
Lloyd B. Jensen, Ph.D.
Carl S. Pederson, Ph.D.

Paul S. Prickett, Ph.D.
John M. Sharf, Ph.D.
Oscar B. Williams, Ph.D.

Health Officers Section

Committee on Health Officers' Salaries

Edward G. McGavran, M.D., *Chairman*,
University of Kansas, Kansas City, Kans.
Dwight M. Bissell, M.D.
Malcolm R. Bow, M.D.

Andrew J. Krog
George C. Ruhland, M.D.
Huntington Williams, M.D.

Committee on Housing

E. R. Krumbiegel, M.D., *Chairman*, Depart-
ment of Health, Milwaukee, Wisc.
Lloyd M. Graves, M.D.

Committee on Professional Education

V. A. Van Volkenburgh, M.D., *Chairman*,
State Department of Health, Albany,
N. Y.
C. F. Blankenship, M.D.
John Hackler, M.D.
E. A. Piszczek, M.D.

Industrial Hygiene Section

All standing committees were discontinued in 1947 and new committees are now being formed through vote of Section members.

Laboratory Section

Coördinating Committee on Standard Methods

Friend Lee Mickle, Sc.D., *Chairman*, State
Health Department, Hartford, Conn.
Thomas Francis, Jr., M.D.
James Gibbard
A. P. Hitchens, M.D.
R. A. Kelser, D.V.M.
Walter L. Mallmann, Ph.D.
Ralph S. Muckenfuss, M.D.
Stuart Mudd, M.D.
A. H. Robertson, Ph.D.
E. S. Robinson, M.D.
Geoffrey Edsall, M.D., (*ex officio*), *Secre-*
tary, Division of Biologic Laboratories,
Boston, Mass.

Referee¹ for:

Chemical Antiseptics — Henry Welch,
Ph.D.
Chemical Disinfectants — Charles M.
Brewer
Detergents—Walter L. Mallmann, Ph.D.

Associate Referee² for:

Antibiotic Agents—Selman A. Waksman,
Ph.D.
Disinfection of Air by Germicidal Vapors
and Mists—O. H. Robertson, M.D.
Disinfection of Air by Ultra-violet Irradia-
tion—Alexander Hollaender, Ph.D.
Fungicidal and Fungistatic Agents—C. W.
Emmons, Ph.D.
Suppressive Measures for the Control of
Dust—Clayton G. Loosli, M.D.

Committee on Salaries

Thomas F. Sellers, M.D., *Chairman*, State
Board of Health, Atlanta, Ga.
George M. Cameron, Ph.D.
George D. Cummings, M.D.
Charles A. Hunter, Ph.D.
Edmund K. Kline, Dr.P.H.
Malcolm H. Merrill, M.D.

Laboratory Section Archivist

Anna M. Sexton, State Department of
Health, Albany, N. Y.

Laboratory Section Representative on the Commisson for the Study of Bio- logical Stains

Edmund K. Kline, Ph.D., Cattaraugus
County Department of Health, Olean,
N. Y.

Committee for the Examination of Germi- cides and Antibacterial Agents

Stuart Mudd, M.D., *Chairman*, University
of Pennsylvania, Philadelphia, Pa.

¹ Referees are members of the Standard Methods
Committee upon which they serve.

² Associate Referees are not members of the Stand-
ard Methods Committee upon which they serve.

Standard Methods Committee on Biology of the Laboratory Animal

Paul A. Moody, Ph.D., *Acting Chairman*,
University of Vermont, Burlington, Vt.

Associate Referees²

Arthur M. Cloudman, Ph.D.
R. G. Daggs, Ph.D.
Ralph W. Mohri, D.V.M.
Gregory Pincus, D.Sc.
Norman J. Pyle, V.M.D.
Paul B. Swain, Sc.D.
George B. Wislocki, M.D.

Standard Methods Committee on Biological Products

Elliott S. Robinson, M.D., *Chairman*,
R.F.D. No. 4, Laconia, N. H.
Donald T. Fraser, M.B., D.P.H.
R. J. Gibbons, M.D.
Harold W. Lyall, Ph.D.
John T. Tripp, Ph.D.
Milton V. Veldee, M.D.

Standard Methods Committee on Diagnostic Procedures and Reagents

Ralph S. Muckenfuss, M.D., *Chairman*,
City Health Department, New York,
N. Y.

(All referees and associate referees to be appointed)

Standard Methods Committee on Diagnostic Procedures in Virus and Rickettsial Diseases

Thomas Francis, Jr., M.D., *Chairman*, University of Michigan, Ann Arbor, Mich.

Referee¹ for:

Atypical Pneumonia—Alto E. Feller, M.D.
Dengue and Sandfly Fever—Albert E. Sabin, M.D.
Encephalitis—William McD. Hammon, M.D.
Inclusion Blennorrhoea—Phillip Thygeson, M.D.
Influenza—George K. Hirst, M.D.
Lymphogranuloma Venereum—Geoffrey W. Rake, M.B.
Mumps—John F. Enders, Ph.D.
Poliomyelitis—John R. Paul, M.D.
Psittacosis and Ornithosis—Karl F. Meyer, M.D.
Rabies—Harald N. Johnson, M.D.
Rickettsial Diseases—Joseph E. Smadel, M.D., and Norman H. Topping, M.D.
Yellow Fever—Richard M. Taylor, M.D., and John Bugher, M.D.

Standard Methods Committee on Frozen Desserts and Ingredients (Joint with the Committee of Food and Nutrition Section)

A. H. Robertson, Ph.D., *Chairman*, State Department of Agriculture and Markets, Albany, N. Y.
James Gibbard
Leon Buchbinder, Ph.D.

Referee¹ for:

Chemical Analysis of Frozen Desserts and Ingredients—J. H. Shrader, Ph.D.
Microbiological Examination of Frozen Desserts—A. H. Robertson, Ph.D.
Microbiological Examination of Ingredients—F. W. Fabian, Ph.D.
Sediment Testing of Frozen Desserts and Ingredients—K. G. Weckel, Ph.D.

Associate Referee² for:

Chemical Determinations of Modified Babcock Methods for Frozen Desserts—W. H. Martin
Chemical Determinations of Stabilizers in Frozen Desserts—F. Leslie Hart
Determination of Overrun in Ice Cream—P. S. Lucas
Microbiological Examination of Condensed and Evaporated Milk—Paul A. Downs, Ph.D.
Microbiological Examination of Dry Milk—Paul S. Prickett, Ph.D.
Microbiological Examination of Eggs—M. Thomas Bartram, Ph.D.
Microbiological Examination of Flavors, Colors, Fruits, and Nuts—M. J. Prucha, Ph.D.
Microbiological Examination of Sugar—H. H. Hall
Sampling for Chemical Determinations—P. H. Tracy, Ph.D.

Standard Methods Committee on Examination of Milk and Milk Products

A. H. Robertson, Ph.D., *Chairman*, State Department of Agriculture and Markets, Albany, N. Y.
Luther A. Black, Ph.D.
Robert S. Breed, Ph.D.
Angel de la Garza Brito, M.D.
Raoul F. Cowley

¹ Referees are members of the Standard Methods Committee upon which they serve.

² Associate Referees are not members of the Standard Methods Committee upon which they serve.

Referee¹ for:

- Chemical Methods for Examining Dairy Products—William A. Queen
 Comparative Tests of Agar Media for Standard Milk Work—S. R. Damon, Ph.D.
 Coördination of Milk Ordinance and Laboratory Work—A. W. Fuchs, C.E.
 Laboratory Equipment — Raymond V. Stone, D.V.M.
 Methods of Counting Bacteria in Dairy Products—A. H. Robertson, Ph.D.
 Methods for Detecting Organisms of the Coliform Group—Albert J. Slack, M.D.
 Methods of Isolating Specific Types of Bacteria in Dairy Products—Mac H. McCrady
 Methylene Blue Reduction Test — C. A. Abele, Ch.E.
 Microbiological Methods for Examining Butter—Ralph V. Hussong, Ph.D.
 Sediment Test—E. H. Parfitt, Ph.D.
 Tests for the Sterility of Dairy Utensils—Walter D. Tiedeman, M.C.E.

Associate Referee² for:

- Methods for the Examination of Cheese—M. W. Yale, Ph.D.
 Methods for Examining Milk for Evidences of Brucella Infection—I. F. Huddleson, Ph.D.
 Methods of Examining Milk for Tubercle Bacilli—William A. Hagan, D.V.M.
 Methods of Identifying Streptococci in Dairy Products—George J. Hucker, Ph.D.
 Phosphatase Test—Professor L. H. Burgwald
 Resazurin Test—C. K. Johns, Ph.D.

Subcommittee on Methylene Blue Reduction and Resazurin Tests:

- C. A. Abele, Ch.E., *Chairman*, Board of Health, Chicago, Ill.
 C. K. Johns, Ph.D.
 E. H. Parfitt, Ph.D.
 A. H. Robertson, Ph.D.
 H. R. Thornton, Ph.D.

Subcommittee on Sediment Testing:

- E. H. Parfitt, Ph.D., *Chairman*, 307 North Michigan Avenue, Chicago, Ill.

- J. O. Clarke
 K. G. Weckel, Ph.D.

Joint Editorial Committee for Standard Methods for the Examination of Dairy Products:

- Robert S. Breed, Ph.D., *Chairman*, New York State Agricultural Experiment Station, Geneva, N. Y.
 A. Parker Hitchens, M.D.
 Albert C. Hunter, Ph.D.
 Friend Lee Mickle, Sc.D.
 Henry T. Scott, Ph.D.

Standard Methods Committee on Examination of Water and Sewage

- Walter L. Mallmann, Ph.D., *Chairman*, Michigan State College, East Lansing, Mich.

Referee¹ for:

- Bacteriological Methods for Water—Mac H. McCrady
 Coliform Group Variants—Charles A. Stuart, Ph.D.
 Microscopic Methods of Water—Theodore A. Olson
 Swimming Pool and Bathing Place Waters—Walter L. Mallmann, Ph.D.

Standard Methods Committee on Examination of Shellfish

- James Gibbard, *Chairman*, Department of Pensions and National Health, Ottawa, Ont.
 Paul Arnehausen
 Victor H. Bertullo, D.V.M.
 Leon Buchbinder, Ph.D.
 Chester T. Butterfield
 Clifford Byrd
 Eduardo Joubanc
 C. B. Kelly, Jr.
 Dorothy Phelps
 Charles E. Renn
 Leslie A. Sandholzer, Ph.D.
 Glenn G. Slocum

¹ Referees are members of the Standard Methods Committee upon which they serve.

² Associate Referees are not members of the Standard Methods Committee upon which they serve.

Maternal and Child Health Section

Committee on Health Standards for Children's Camps

Milton I. Levine, M.D., *Chairman*, 302 West 12th Street, New York, N. Y.
Helen F. Leighty
L. B. Sharp, Ph.D.

Committee on Membership and Fellowship

Paul R. Ensign, M.D., *Chairman*, State Board of Health, Topeka, Kan.
Hester B. Curtis, M.D.
Marcia Hays, M.D.
Edythe P. Hershey, M.D.

Herbert R. Kobes, M.D.
Kenneth S. Landauer, M.D.

Program Committee

Myron E. Wegman, M.D., *Chairman*, Louisiana State University, New Orleans, La.
Katherine Bain, M.D.
Samuel R. Berenberg, M.D.
Amos Christie, M.D.
Edward Davens, M.D.
Samuel B. Kirkwood, M.D.
Marie-Louise Pareti, M.D.
Leon Sternfeld, M.D.

Public Health Education Section

Regional Committees

Committee on Public Health Education Problems in the Far West Region

Howard W. Lundy, Dr.P.H., *Chairman*, State Department of Health, Seattle, Wash.
Ann W. Haynes, Section Council Sponsor, State Department of Health, San Francisco, Calif.

Membership:

All Section Fellows and members in the States of the Far West Region—Washington, Oregon, Nevada, California.

(Fellows and members of Alaska, the Territory of Hawaii, and the Philippine Islands may work with this group although essentially not a part of the Far West Region plan.)

Committee on Public Health Education Problems in Latin America

Philip L. Riley, *Chairman*, C.I.A.A., 6616 Commerce Dept. Bldg., Washington, D. C.
Alice M. Johnson, Section Council Sponsor, U. S. Public Health Service, Washington, D. C.

Membership:

All Section Fellows and members in Puerto Rico, Mexico, and South American countries.

Committee on Public Health Education Problems in the Middle States Region

Hugh Masters, *Chairman*, Kellogg Foundation, Battle Creek, Mich.
Lewis C. Robbins, M.D., Section Council Sponsor, U. S. Public Health Service, Chicago, Ill.

Membership:

All Section Fellows and Members in the States of the Middle States Region—Minnesota, Wisconsin, Iowa, Missouri, Illinois, Indiana, Ohio, Michigan.

Committee on Public Health Education Problems in the Northeastern Region

Homer N. Calver, *Chairman*, 1790 Broadway, New York, N. Y.
Bess Exton, Section Council Sponsor, National Education Association, Washington, D. C.

Membership:

All Section Fellows and members in the States of the Northeast Region—Maine, Vermont, New Hampshire, Massachusetts, New Jersey, Rhode Island, West Virginia, Maryland, Pennsylvania, New York, Washington, D. C., Connecticut.

**Committee on Public Health Education
Problems in the Northwestern Region**

Edna Gerken, Chairman, U. S. Office of the Interior, Chicago, Illinois.

Mabel Rugen, Ph.D., Section Council Sponsor, University of Michigan, Ann Arbor, Mich.

Membership:

All Section Fellows and members in the States of the Northwest Region—Montana, Idaho, Utah, Wyoming, Colorado, Nebraska, North Dakota, Kansas, South Dakota.

**Committee on Public Health Education
Problems in the Southeastern Region**

Helen A. Martikainen, *Chairman*, U. S. Public Health Service, Richmond, Va.

Eunice Tyler, Ph.D., Section Council Sponsor, University of North Carolina, Chapel Hill, N. C.

Membership:

All Section Fellows and members in the States of the Southeast Region—Kentucky, Virginia, North Carolina, Tennessee, South Carolina, Arkansas, Florida, Mississippi, Alabama, Georgia, Louisiana.

**Committee on Public Health Education
Problems in the Southwestern Region**

Opal Hartline, Ph.D., *Chairman, Pro Tem*, City-County Health Unit, El Paso, Tex.

J. Louis Neff, Section Council Sponsor, American Cancer Society, Houston, Tex.

Membership:

All Section Fellows and members in the States of the Southwest Region—Arizona, New Mexico, Texas, Oklahoma.

Cross Section Committees

**Committee on Community Organization
for Health Education**

Clair E. Turner, Dr.P.H., *Chairman*, National Foundation for Infantile Paralysis, New York, N. Y.

(Personnel to be appointed)

**Committee on Coördination of Public
Health Education Section with all
Other Sections of the A.P.H.A.**

Muriel F. Bliss, Ph.D., *Chairman*, Hartford Tuberculosis and Public Health Society, Hartford, Conn.

(Personnel to be appointed)

**Committee on Convention Public Health
Education Practices**

Materials and Publicity

Rae K. Shoemaker, *Chairman*, National Foundation for Infantile Paralysis, New York, N. Y.

Sallie Bright, *Co-chairman*, National Publicity Council for Health and Welfare Services, New York, N. Y.

**Committee on Post-war Planning in
Public Health Education**

Mayhew Derryberry, Ph.D., *Chairman*, U. S. Public Health Service, Washington, D. C.

(Personnel to be appointed)

Motion Picture Theatre

Thomas C. Stowell, *Chairman*, State Department of Health, Albany, N. Y.

MARCH RECORD FOR NEW MEMBERS

The membership department of the Association has been boasting ever since the mail was distributed on March 24. On that day the 237th application of the month for membership in the Association was received. Another record was broken. By the end of March 299 applications had come in, a record never before equalled. Between January 1 and March 31, 610 persons applied for membership. This is more than the total number of new members during any of the years, 1929, 1931, 1932, and 1933.

And who gets the credit for this new record? The members of the Association themselves. Half of these new applications came on formal nomination of members, nearly 50 used the *Journal* application blanks and must also have been inspired by members. Ten per cent came in through affiliated societies.

A few more statistics! Nearly one-fifth of the new members applied for admission to the Public Health Nursing Section, more than 30 each to the Laboratory, Health Officers, and Engineering Sections, 29 to Public Health Education, and the remaining 113 were divided among the 7 other sections and unaffiliated.

Geographically all but 12 states are represented by March's 299 members. In addition, Alaska, Hawaii, and Puerto Rico are represented, as well as Brazil, Canada, China, Ecuador, Mexico, and the Philippines.

The ages of the applicants range from 21 to 75 and, by way of illustrating the public health worker's detachment from the more mundane affairs, one applicant was reported born in February, 1947, and one in August, 1947.

The total membership of the Association at the end of March was 10,830. The goal is 12,000 by the time of the annual meeting in October. For the list of the 299 March newcomers see p. 617.

CLEANLINESS EDUCATION

Cleanliness Training and Health Education, the monthly double page leaflet of the Cleanliness Bureau of the American Association of Soap and Glycerine Producers (11 West 42nd St., New York 18) has a lot of fertile ideas for the health educator. The February issue for example, tells the story of "The Search for Health," a health project developed from the fifth grade of a school in Escanaba, Mich. The interest of the children was aroused through ancient history—the witch doctor, the medicine man, the Roman baths, the Black Death of the Middle Ages. At the end of the project they had not only widened horizons but a broad background of health knowledge.

Among other items in the February issue are "Schenectady's Exhibit 'A' in Public Building Cleanliness" and "Cincinnati Schools Teach the Reason for Cleanliness."

FOOD SOUTH OF THE EQUATOR

Those whose interest in food and nutrition problems goes beyond their own doorsteps will find *Paraguayan Rural Life: Survey of Food Problems* rewarding. A special report of the Food Supply Division of the Institute of Inter-American Affairs (Washington, D. C.), it is a good, brief sociological picture of Paraguay, illustrated with many photographs. Among other uses this would be excellent laboratory material for high school nutrition, geogra-

phy, or social science classes. Other special reports of the Division are available, discussing food and agricultural conditions in Brazil, Haiti, Honduras, Panama, and Venezuela.

CONNECTICUT CANCER SOCIETY

HANDBOOK

The Connecticut Cancer Society has published a loose leaf reference manual for its officers and workers. Here is excellent background material to orient workers in the history of their organization and the place it fills in cancer education. The outstanding dates of both the National and Connecticut Cancer Societies are mentioned, the organization of the State Society and the work of the State Health Department's Cancer Division. There are instructions for organizing a district, for carrying on an education program, for developing publicity. The printing, paper, typography and layout are all good. Not the least of its virtues is that it is loose leaf, for ease in being kept up to date. The impressive looking map with which it starts puzzles us. It needs more extensive legends to be fully understandable.

The offices of the Connecticut Cancer Society are at 95 North Main Street, Waterbury 14.

MILESTONES IN TUBERCULOSIS CONTROL

The Long Adventure, in its 31 pages, makes poetry in prose of the daring and stirring adventure of penetrating the mystery of tuberculosis. Beginning with Hippocrates and his first detailed descriptions of the disease, there are short but meaty chapters on Laënnec, Villemin, Pasteur, Koch, Roentgen, Theobald Smith, Trudeau, Forlanini, Murphy, and Philip, in addition to recent moderns such as Welch, Biggs, Osler, and Flick. Gaily illustrated in a bright yellow cover, this is an inspired piece of historical writing in the

service of present-day understanding and support of tuberculosis control measures. The author is Marie McCall; the publisher, the National Tuberculosis Association, 1790 Broadway, New York 19.

THE OTA TEST AND FREE RESIDUAL CHLORINATION

The following is of interest to all public health workers concerned with water treatment and supplies and is taken from *Health News*, Vol. 24, No. 8 (Feb. 24), 1947, of the New York State Department of Health:

Water supply officials, generally speaking, have not adopted either the orthotolidine arsenite (OTA) test or the practice of superchlorination to the extent which seems justified, according to a review of current chlorination practice in New York State. Wider application of these modern procedures is warranted by the numerous advantages they offer.

ADVANTAGES OF THE OTA TEST

The conventional orthotolidine (OT) test has been of great value in the control of the chlorination of water. It gives erroneous results, however, when manganese or nitrites are present in the water being tested. Furthermore, the results when correct represent the total concentration of residual chlorine and not the proportion of free residual chlorine of high disinfecting power or the proportion of residual combined chlorine.

The new test (OTA) gives accurate results in the presence of interfering substances in the water and, of greater importance, provides the means of controlling the chlorination of water so as to produce free residual chlorine. It affords, therefore, a means of determining when superchlorination or free residual chlorination reactions occur; that is, when the deleterious influence of organic matter, high pH and low temperature of the water have been nullified and conditions which will insure rapid disinfection have been created.

There are a large number of water supplies to which ammonia is not added but in which, in the raw state, there is sufficient ammonia, accompanied by organic matter, to result in the formation of chloramines or combined residual chlorine; in such instances, operators have not realized the need of main-

taining higher concentrations of combined residual chlorine because of its lesser disinfecting action. In other instances, it has been found that a minor increase in the dose of chlorine will result in formation of free residual chlorine with the benefits outlined below.

The OTA test, therefore, should be used in connection with the chlorination of all water supplies to disclose basic information. It need be made only a few times a week if the "flash test" is used each day to disclose the approximate concentration of free residual chlorine.

SUPERCHLORINATION OR FREE RESIDUAL CHLORINATION

Free residual chlorination has been used primarily at water filtration plants because the detention period in coagulation basins or clear wells has been sufficient for the completion of secondary reactions before the water reached the consumer. On the other hand, the absence of a filtration plant may create conditions which can best be overcome by the use of free residual chlorination. This relatively new treatment procedure should be utilized more generally for the treatment of unfiltered surface supplies, especially when treated water may be stored in a reservoir or basin for two hours or more to permit such secondary actions as the control of algae, bleaching, and the precipitation of iron, manganese, and organic matter coagulated by chlorine.

The significant fact is that free residual chlorination achieves all these benefits together with more effective disinfection, production of stable residual chlorine, and elimination of chlorinous tastes. Formerly, stable chloramines (chlorine-ammonia treatment) were not effective disinfectants; any increase in the concentration of chloramines or combined residual chlorine to secure effective disinfection frequently caused chlorinous tastes.

For these reasons, it is important that water supply officials appraise the supplies under their supervision to determine how best this improved disinfecting process may be used. Higher capacity chlorinators will be needed most likely in many instances to permit the practice of free residual chlorination which offers the following additional advantages: destruction by oxidation of taste- and odor-producing compounds; control of deleterious growths inside water mains; and the prevention of biochemical corrosion through the destruction of organisms associated with the production of organic acids or the reduction of sulphates to sulphides.

ANOTHER APPROACH TO INTERGOVERNMENTAL COÖPERATION

In November ("Grass Roots Planning," p. 1327), we suggested that you watch for the report of the Colquitt County (Georgia) Council on Intergovernmental Relations. The third in the series of Spelman Foundation supported inquiries into ways in which local government can be accommodated to the 20th century, this one places main emphasis upon a coördinated agricultural plan.

It also includes, however, an exploratory study in the field of public health. It finds that the experience of a city-county health department has much to contribute to coördination in other areas of public service.

This report of a field laboratory for study and experiment in intergovernmental relations can be secured from Colquitt County Council on Intergovernmental Relations, Moultrie, Ga.

REPORT FROM HAWAII

Two reports have come out of Hawaii indicating that its civilian services have gone back to a peacetime basis after the upheavals of Pearl Harbor. The first is the *Annual Report of the Territorial Board of Health* for the year ending June 30, 1946, by its President, C. L. Wilbar, Jr., M.D. Its nearly 150 pages contain a very complete report of the Territory's house-keeping and the special health problems that it faces in the immediate future.

The second is a report on *School Health Programs in the Territory of Hawaii* by its Chamber of Commerce. The Chamber has an active Public Health Committee directed by R. S. Nebelung, Dr.P.H. Its Committee on School Health, with numerous subcommittees, has developed this long-range school health program designed to give the child an opportunity to attain his optimum state of physical fitness.

ANNUAL REPORTS

Oklahoma Health Department—The cover of the Oklahoma State Department's *Biennial Report* has an attractive photograph of the department's building in Oklahoma City superimposed upon the state map and outlined in a bright, cheery red. Inside the covers the attractive layout continues with photographs and charts telling as much of the story as possible. There is no reason why the citizens of Oklahoma should any longer lack information about their Health Department—what it does and what it needs to carry out its long-range program.

Hartford (Conn.) Health Department—The *Triennial Report* of the Hartford City Health Department comes in an apple green attractive cover, and drawings and a wealth of photographs illustrating the work of the department. It points out that Hartford's public health history goes back to 1784 when the Court of Common Pleas appointed a committee to investigate nuisances. The city's first Board of Health was established in 1885; since that time annual or biennial reports have been continuous.

The citizens of Hartford who read this report should be in no confusion as to the services provided by their Health Department.

REPORT FROM INDIA

The Secretary of State of the United States sends us, from the Consulate General at Calcutta, India, a *Summary Report of the All-India Institute of Hygiene and Public Health* for the 5 year period 1940 to 1944, together with a prospectus of the courses given at the Institute.

During all this period John B. Grant, M.D., was Director of the Institute, on loan from the Rockefeller Foundation which has also contributed extensively to the support of the Institute during these years.

Even a casual study of the report and prospectus, and particularly of the research projects carried on, reinforces the conviction that this is "one world" in public health as well as in other matters.

The introduction of the report gives a good brief history of public health education and the Institute. Between 1910 and 1922 Calcutta University, although proper facilities for instruction were lacking, maintained an Institute for the Diploma in Public Health. In 1922 the D.P.H. course was transferred to the School of Tropical Medicine. Finally in 1933 the All-India Institute was organized, and in 1939 Dr. Grant became its Director for a period of more than 5 years.

ULSTER COUNTY (N. Y.) REPORTS

ITS PROGRESS

The February *Journal* (p. 245) told you of the organization of the Ulster County (N. Y.) Health Department under the 1946 legislation that encourages, with generous state aid, the development of full-time county health departments to replace the numerous uncoordinated part-time town and village departments.

This new county health department apparently intends to document its history fully. Credit Lines has just received its first monthly report for January, 1947. Here is outlined briefly how the department was organized and the staff taken over from the state district office which had previously served the area. A complete list of personnel is shown. Public health nurses actually on the job were in the ratio of one to 6,200 population; the full complement of nurses with all vacancies filled would be one per 5,100 population. Environmental sanitation personnel—engineers, veterinarians, and sanitary inspectors—were in the ratio of approximately one per 15,000 population.

Another interesting note is that the

largest city in the county and two additional towns have already abolished their own separate boards of health, a development that is permissive but not mandatory under the new law.

TYPHOID FROM ICE CREAM

The Borough of Aberystwyth, Wales, was the center of an outbreak of typhoid fever during the summer of 1946. The vector was traced to an ice cream supply manufactured and sold by a licensed vendor resident in the Borough. Investigation disclosed the fact that the vendor was a urinary carrier of typhoid—a condition which apparently had persisted since an attack of typhoid in 1938.

During the investigation of the epidemic, water and milk were ruled out quickly and attention was focused on the ice cream supply. The epidemic stopped abruptly upon the barring of further sales of ice cream. Over 200 cases in all were reported. The account of the epidemic in detail is contained in the January 25, 1947, issue of *The Medical Officer*, a British publication.

WORTH ACQUIRING

The latest of the National Publicity Councils How-to-Do-It publications is *Radio—How, When and Why to Use It*. By Beatrice K. Tolleris (who will be remembered as the author of *Annual Reports—How to Write Them*), it is a manual on non-commercial broadcasting that analyzes the factors determining when a community agency should take to the air to win understanding and support. Once that has been decided, the techniques for getting sustaining time and the uses of the various programs, such as interview, round table, dramatization, and on-the-spot broadcast are outlined, as well as program promotion. It is written especially for the busy executive. National Publicity Council, 130 East 22nd Street,

New York 10, \$1.00 per copy. Progressively reduced rates for orders of 10 or more copies.

Food the World Over—Credit Lines has already mentioned (July, 1946, p. 803) the "Food the World Over" series of the Brooklyn Visiting Nurse Association (138 So. Oxford St., Brooklyn 17, N. Y.). The fourth of the series deals with the food habits of Polish groups and suggests ways of building their customary dietary up to everyday nutrition standards. These booklets are planned specifically for professional workers as an aid in nutrition teaching. The earlier booklets in the series deal with foods used respectively by Puerto Rican, Italian, and Jewish groups; later ones will cover Syrian and sectional American dietaries. 20 cents per copy.

Facts about Syphilis and Gonorrhea, *Wedding Plans*, and *Protecting the Unborn Baby from Syphilis* are three leaflets of the Industrial Hygiene Division of the U. S. Public Health Service. Their text is: "VD may not take a man off the production line now—but the eventual loss if he goes untreated will be high." Intended especially for distribution to industrial workers. Sample copies free from U. S. Public Health Service, Washington, D. C. Quantity orders \$1.50 per 100, and \$2.50 per 100 for *Facts about Syphilis and Gonorrhea* from Superintendent of Documents, Govt. Ptg. Office, Washington 25, D. C.

A series of 10 nutrition charts has been prepared by the U. S. Bureau of Human Nutrition and Home Economics as a visual teaching aid for nutrition classes and wall exhibit use. Done in yellow and black on heavy white paper, the charts have photographs of laboratory animals which show the importance of a well balanced diet. The theme is "Food makes a difference." Available in sets only at 75 cents a set, Govt. Ptg. Office, Washington 25, D. C.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted. All books reviewed in these columns may be purchased through the Book Service.

The Personality of the Preschool Child. A Child's Search for His Self—By Werner Wolff, Ph.D. Foreword by Mary Fisher Langmuir. New York: Grune & Stratton, 1946. 341 pp. Price, \$5.00.

This record of extensive explorations into the various aspects of a young child's personality may be somewhat overwhelming for the average public health worker who is unfamiliar with the experimental techniques used and who may be skeptical of the conclusions drawn. But its basic point of view is one which all such workers should have: viz., that the child's social behavior, his emotional development, his intellectual activities, all must be understood from the point of view of his own culture, from how *he* "sees," "feels," or "understands" things. The author presents a concept of two worlds, that of child and that of adult, and illustrates the tremendous gap which lies between them. He warns us not to transfer the concepts of adult psychology to child psychology. Emphasis is placed on the need for bridging the gap between the so-called worlds and many valuable hints are given for doing so. Misconceptions of the nature of the young child are freely discussed and the dangers of relying too heavily on the fact that the child's growth follows a definite pattern. The need for understanding the unique pattern of personality in each individual child is also made clear. A concept that "all expressions of personality by the young child seem to be varieties on one theme; the child's search for his self" is also emphasized. It is these general con-

cepts which all readers will find stimulating and provocative.

The book is fairly well documented.
LEONA BAUMGARTNER

Scheduled Salaries for Social Work Positions in Hospitals in New York City, December, 1946—By Ralph G. Hurlin. New York: Russell Sage Foundation, 1947. 42 pp. Price, \$.40.

This pamphlet is issued in advance of a wider inquiry relating to social work salaries in medical agencies of New York City generally.

Its opening statement says, "The results are being made available in advance of the wider inquiry because it is believed they will be immediately useful to both employing agencies and social workers in evaluating present salaries."

Salary schedules, with related employment conditions, are shown for voluntary hospital social service departments as well as for city, state, and federal hospitals in the city. Generally speaking, salaries are highest in the federal hospitals and lowest in the city hospitals. In the voluntary hospitals, \$2,400 has come to be a standard minimum annual salary for case workers, representing in many instances an increase of one-third within the past year. The minimum for the same position is \$3,397 in veterans' hospitals; \$3,036 in Army and Navy hospitals; \$2,268 in state mental hospitals; and \$2,160 in city hospitals.

Among Mr. Hurlin's conclusions is that low salaries are responsible for unfilled positions in the social work departments of hospitals in New York

City. This is true in spite of the fact that nearly all workers received salary increases during 1946. The hopeful note is a "growing recognition of the inadequacy of social work salaries in relation to the nature of the work and the preparation asked of social workers."

This study and the larger study of which it is a part have much to contribute to those who are studying public health salaries in relation to current living costs, personnel shortages, and qualification standards of public health workers.

MARTHA LUGINBUHL

Morton's Memoir—By W. T. G. Morton. New York: Henry Schuman, 1946. 24 pp.

John Fulton of the Historical Library, Yale Library, has given us a first reprint of Morton's charming letter to the Academy of Sciences at Paris. It is published on the occasion of the centennial of ether discovery. In this *Memoir*, Morton presented a simple and direct narrative of his experiments with the use of nitrous ether in order to refute the claims of Wells and Jackson to its discovery. It documents very properly Robinson's history of anesthesia.

CHARLES E. SHEPARD

Health Examinations — By the Special Committee on Preventive Medicine of the New York County Medical Society. 1945 ed. 144 pp. *Pocket Manual*, 3½ x 7½ in. Free from publisher.

When the House of Delegates of the American Medical Association in 1922 recommended the routine periodic health examination as a practical contribution to preventive medicine, an important new door was opened to physicians for public service. This new edition of the New York County Medical Society's manual for the general practitioner is a useful aid to the examining physician.

It considerably clarifies the technique

of some of the less well known features of these examinations, and will considerably extend for most physicians the field of inquiry. It also gives significant help in interpretation of findings. These examinations become more comprehensive and meaningful under the guidance of the eighteen experts who have written the fourteen chapters comprising the book.

These chapters are separately devoted to the premarital examination, the infant, the child under six, the school age child, with an excellent special chapter devoted to the emotional development before adolescence, and another chapter covering the psychological aspects during adolescence. The adult is considered in the three age periods—youth, middle age, and senescence—with a special writer taking up each aspect of the subject.

If general practitioners would seriously study the information this little book contains, their work in detecting the presence and cause of health frailties and the early signs of significant disease would be greatly enriched.

J. G. VAUGHAN

Proceedings of the Conference on Preventive Medicine and Health Economics—University of Michigan. Ann Arbor, Mich.: University of Michigan, 1947. 245 pp. Free.

In the early fall of 1946, teachers of preventive medicine from most of the medical schools of the United States and Canada met at the University of Michigan. Drs. John Grant and Alan Gregg of the Rockefeller Foundation with their opening presentations of "Toward Health—Certain Trends," and "Transition in Medical Education," vitalized the issues that are facing us in medicine today. The first half of the conference was given over to the subject of the teaching of preventive medicine. The formal papers, discussion, and committee reports dealt with the

points of view relative to philosophies and objectives as well as with content and teaching methods.

The remainder of the conference was devoted to the subject of health economics which was presented under the following headings:

1. The Developing Field of Health Economics
2. Educational Needs in Health Economics
3. Health Economics in the Medical Curriculum
4. Problems of Personnel

As a consequence of the varied background and experience of the teachers of preventive medicine, many points of view were brought to bear on the problems presented. Crystallization and rigid definition were not achieved, attempted or desired. The members of the conference, however, had their first real opportunity to learn what was being done elsewhere and to compare and evaluate their own programs with those of their confreres in other parts of the country. Equally important was the consideration of the developing field of health economics and the possible rôles of the teacher of preventive medicine in teaching this subject.

In a review such as this, it is impossible to list the papers presented or to summarize and review them critically. The proceedings have been widely distributed. A careful study of the material is distinctly worth while for those interested in teaching preventive medicine and health economics.

LLOYD FLORIO

Nursing Care in Chronic Diseases

—By *Edith L. Marsh, R.N., S.C.M.*
Philadelphia: Lippincott, 1946. 237 pp. Price, \$3.00.

The kernel of this valuable little book lies in this sentence: "It is necessary to create opportunities for those chronically ill people who may still be useful to themselves and the community, and to give the benefit of excellent nursing care and expert medical attention to

those patients whose chronic illness means hospitalization." It is dawning on the medical and nursing professions, the author points out, that "care of chronic illness is more than merely making patients comfortable for the rest of their days."

Miss Marsh then proceeds to tackle the whole problem of home, foster home, and boarding home care as well as hospital service for the chronically ill. She presents ways of making these services more effective, bringing out the point that this group needs companionship, supportive measures, such as physical and occupational therapy, good food, and recreation.

The nursing care of special conditions comprises the main part of this book and is realistic, helpful, and simply described. Public health nurses as well as nurses in private practice will find these chapters worth reading in view of the growing load of elderly patients. The practical suggestions resulting from Miss Marsh's wide experience are worth adopting.

The outstanding quality of this book, however, is its spirit which gives the reader lessons not only in enlightened nursing care, but in sympathetic understanding of those whose physical or mental activities, or whose days of life, are limited. It is a good book for a nurse to own.

This reviewer regrets that Miss Marsh did not describe the place, training, and supervision of the practical nurse (or attendant) in the care of the chronically ill.

DOROTHY DEMING

How Can We Teach about Sex?—

By *Benjamin C. Gruenberg.* *New York: Public Affairs Committee, 1946. 32 pp. Price, \$.10.* (A special edition published for the American Social Hygiene Association is available at 10 cents at the Association's headquarters, 1790 Broadway, New York 19, N. Y.)

Here is a useful and inexpensive out-

line of basic concepts and practices in a widely misunderstood field. Controversies over who should be responsible for sex education of youth—the home, church or school—have been allowed to obscure the generally agreed on thesis that sound education and guidance in the wise use of sex are essentials. As a result, far too little has been or is being done by any or all of the three logical agencies.

Authorities concur in the belief that the home should be the primary source for this training, but that school and church should furnish valid and usable supplemental facts and philosophy along scientific and ethical lines. They also agree that isolated courses designated as "sex hygiene" or "social hygiene" are undesirable and that curricular efforts should be to integrate, i.e., to deal with problems having sexual connotations in whatever courses those problems naturally arise. Biology, botany, home economics, health and physical education, and all of the newer sociological courses such as those designated "family life," "human relationships," *et al.* are good examples.

Gruenberg is one of the leaders and pioneers in developing the fundamental thinking and practices of sex education. Along with Balliet, Bigelow, Exner, Galloway and their confreres, he has contributed several text and source books to the growing armamentarium available for school and home use. This most recent of his publications was subjected to wide consideration, discussion and criticism by many of his colleagues during its writing and re-writing. The resulting essence is a readable, stimulating and utilitarian summary.

RAY H. EVERETT

Nutrition and Diet Therapy, A Textbook of Dietetics—By Fairfax T. Proudfit and Corinne Hogden Robinson. (9th ed.) New York: Macmillan, 1946. 782 pp. Price, \$3.75.

This ninth edition of a well known nursing text has a number of new features to enhance its value for students in schools of nursing, and as a reference book for graduate nurses and dietitians. The book is arranged in five sections—as follows: "Normal Nutrition," "Normal Nutrition in Special Conditions," "Diet Therapy," "Practical Applications of Nutrition: Elementary Cookery," and "Recipes." An appendix containing suggested course outlines, dietary case study outline, food composition tables, and other tables adds to the usefulness of the book. A new chapter, "Feeding the Aged," gives consideration to the special needs of an ever increasing proportion of our population, and presents many sound and practical guides for their diet.

The bibliography at the close of each chapter has been brought up to date. The projects and review questions included place emphasis on a normal diet and optimum nutrition for all.

HAROLD R. SANDSTEAD

Negro Housing Needs—By Joseph H. Bunzel. Pittsburgh, Pa.: Pittsburgh Housing Association, 1946. 32 pp. Price, \$.50.

This monograph is concerned not only with a study of Negro housing needs in Pittsburgh and Allegheny County, but also with possible solutions to meet these needs. The author has tackled this problem of housing in an attempt to find objective and factual data to support the many general statements which are made about housing for Negroes. He does this not only by using Bureau of the Census material, but also by block studies, estimates of costs, population changes, the employment picture and studies made by such agencies as the National Housing Agency and War Housing Center. Thus he has facts to support such statements as: (a) twice as many of the housing

units for Negroes as for whites are substandard; (b) among Negro tenants, there are a greater number of large families than among the white population; (c) private enterprise has made few dwelling units available to the Negro population in the preceding 5 years; (d) the average rent paid by Negroes is higher for accommodations far inferior to those procured by whites; and (e) Negroes of low income need more bedrooms than white families of similar economic status. Incidentally, as a result of this study, the author suggests that in the 1950 Census, both the number of rooms and bedrooms be taken into consideration in order to facilitate realistic and comparative housing statistics.

The suggestions for solution of the needs indicated made by the author are sound and in keeping with accepted practices. This booklet should serve as a guide to other communities interested in this problem. It also may be used to advantage by public health workers, social workers, and community leaders.

Unfortunately the booklet is mimeographed and paper covered. Some of the tables could have been much more attractively arranged; and in certain sections the writing could have been more polished. The reviewer also has an emotional quirk which makes him object to the title "Negro Housing" just as he objects to "Negro health" and "Negro churches."

PAUL B. CORNELLY

Aging Successfully — By George Lawton. New York: Columbia University Press, 1946. 266 pp. Price, \$2.75.

Are you growing older? Do you pretend that growing older is something that happens to someone else, or are you willing to accept the ultimate fact? If you want to "get on" successfully, this book is a good prescription ad-

ministered to you in mild and tasteful dosage. It is not about sick old people but rather about just people who grow older with all their existing complexes and psychological problems. The author presents his formula from a background of rich experience as student of gerontology and as a psychological counselor on problems of maturity. His style is charming and his message is optimistic. The book is happily free from terrifying statistics on why old people get sick and die, and is devoted rather to how aging minds can do so successfully. The ten hints given in the Epilogue are golden rules of behavior for those who wish to grow older successfully. CHARLES E. SHEPARD

Facts About Nursing, 1946—(9th ed.)—New York: Nursing Information Bureau, 1946. 112 pp. Price, \$.35.

"All who read, write, speak or think about nurses and nursing" will find essential and authoritative statistical information in this, the ninth, edition of the nursing profession's yearbook. Nurses constitute the largest occupational group working for health, and in 1945 added 50,000 new members licensed to practise under state law. Teachers only exceed their numbers among all occupations for women. A yearbook is therefore, amply justified.

Some of the facts about public health nursing do not present as bright a picture as the overall statistics would lead one to expect. There were only 20,672 public health nurses counted in 1946, and only 5,633 of these, or about 28 per cent, had completed a year or more of study in an approved public health nursing program. (Perhaps further study of the statistical tables of comparable salaries would offer one explanation of this.) It is also noted that there were still 1,133 counties in the United States and 23 cities without public health nursing services in 1946.

This is just a sample of the thought-provoking figures supplied by the yearbook. One can learn how many nurses there are, where they are employed, what they are paid, something of the personnel policies in force in their lines of employment, but what they *do*—how many patients they care for, visits they make, how much time they spend on duty—these facts are left to the imagination. Will the time ever come when a yearbook can give the reverse of the picture—the summary of services rendered to the American people by this stupendous working force?

DOROTHY DEMING

The Social Work Year Book—
By Russell M. Kurtz. (9th ed.) New York: Russell Sage Foundation, 1947. 714 pp. Price, \$3.50.

This encyclopedia of social welfare interest and activity includes 79 articles by six authors. Besides being a handbook of current information about activities in various related fields for the professional worker, the volume gives the non-professional reader an understanding of the social problems that challenge citizen attention, and of the programs devised to deal with them. A significant development noted by the authors is the growth in services due both to new needs created by the war

strains and to increased understanding by the public of the value of social services. Shortages of professional personnel have made it impossible for most agencies to meet the demands for service.

Coverage is limited to the United States except in three articles: Canadian Social Work, which is included for the first time, International Social Work, and Foreign Relief and Rehabilitation.

Wilson G. Smillie, M.D., writes cogently on public health, outlining the respective functions of local, state, and federal governments in providing standard health services. Included also is a picture of public health in the post-war period—the new concept of the advantages of nation-wide coördinated research, as well as the recognized need for an organized prepayment plan for family care to replace the “fee-for-service” basis if the average man is to secure adequate preventive and clinical care.

The book also includes a list, with brief descriptions, of 442 national voluntary and 79 governmental agencies in the United States.

This is an invaluable tool for the public health worker no less than for the worker in many related fields. It is, besides, much more thrilling than its prosaic title. MARTHA LUGINBUHL

BOOKS RECEIVED

Listing in this column acknowledges the receipt of books and our appreciation to the senders. Space and the interests of readers will permit review of some, but not all, of the books listed.

ANNUAL REPORT OF THE FEDERAL SECURITY AGENCY (Section Six). Social Security Board. Washington: U. S. Gov. Ptg. Office, 1947. pp. 423–533. Price, \$.25.

APHASIA: A GUIDE TO RETRAINING. By Captain Louis Granich. New York: Grune & Stratton, 1947. 108 pp. Price, \$2.75.

CHILD-LABOR-ON-FARMS PROGRAM IN OPERATION DURING SUMMER SEASON, 1946. Report by New York State Department of

Labor and sponsored jointly by New York State Farm Labor Operating Committee. 99 pp. Free from above (80 Centre Street, New York City).

ETHICS—WITH SPECIAL APPLICATION TO THE NURSING PROFESSION. By Joseph B. McCallister, Ph.D. Philadelphia: Saunders, 1947. 442 pp. Price, \$2.75.

FUNDAMENTALS OF CLINICAL NEUROLOGY. By H. Houston Merritt, M.D., Fred A. Mettler,

- M.D., Ph.D., and Tracy Jackson Putnam, M.D. Philadelphia: Blakiston, 1947. 289 pp. 96 illus. Price, \$6.00.
- THE FUTURE OF HOUSING. By Charles Abrams. New York: Harper & Brothers, 1946. 428 pp. Price, \$5.00.
- GROWING HEALTHFULLY—A TEACHING UNIT FOR GRADES I-XII (revised 1946). By Mabel E. Rugen, Ph.D. New York: National Tuberculosis Association, 1946. 13 pp. Available from state and local tuberculosis associations.
- HEATING VENTILATING AIR CONDITIONING GUIDE 1947. Vol. 25. New York: American Society of Heating and Ventilating Engineers, 1947. 1282 pp. Price, \$6.00.
- HOME ECONOMICS. By Kathyryne T. Healey. Boston: Bellman Publishing Company, Inc., 1946. 24 pp. Price, \$.75.
- INTERNATIONAL HEALTH CONFERENCE. NEW YORK, N. Y., JUNE 19 TO JULY 22, 1946. Report of the United States Delegation Including the Final Act and Related Documents. Department of State. Washington: U. S. Gov. Ptg. Office, 1947. 145 pp. Price, \$.35.
- LABORATORY CONTROL OF WATER PURIFICATION. By Charles R. Cox. New York: Case-Sheppard-Mann Publishing Corp., 1946. 386 pp. Price, \$4.00.
- LET'S TEACH DRIVING—AN ADMINISTRATIVE GUIDEBOOK. Washington: National Commission on Safety Education of the National Education Association, 1947. 135 pp. Price, \$.50.
- MANUAL FOR SEWAGE PLANT OPERATORS. Prepared by Texas Water Works and Sewerage Short School. Lancaster, Pa.: Lancaster Press, Inc., 1946. 435 pp. Price, \$3.50.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Cautious Progress—BCG vaccination was scrutinized by a select committee of experts who recommended that a study be made—and begun this year—of the value of prophylaxis in several exposed groups, among them hospital staffs. For the present it was recommended that the vaccine be not furnished to general practitioners for use with individual patients. More research is needed, the committee decided.

ANON. Report of a Conference on BCG Vaccination. *Pub. Health Rep.* 62, 10:346 (Mar. 7), 1947.

In Lieu of the Poor-Farm—British M.O.H.'s consider the addition of geriatrics to their public health services. Suitable housing for the able; hostels for those with minor mental or physical infirmities; hospitals for the chronic sick among the aged—these are the facilities proposed.

ALLISON, S. F. The Welfare of Old People. *J. Roy. San. Inst.* 57, 2:102 (Mar.), 1947.

You've Heard of the Capacitron, of Course—Something new for sanitary inspectors to worry about! It seems that raw food subjected to a flash of penetrating electrons becomes immune to spoilage. The process need not materially increase the cost of the preserved product, say the writers.

BRASCH, A., and HUBER, W. Ultrashort Application Time of Penetrating Electrons. *Science.* 105, 2718:112 (Jan. 31), 1947.

How Are Your Knackeryards?—British sanitarians are disturbed over the condition of the places where ancient, or deceased animals are disposed of—to make dog meat apparently. The usual sanitary conditions, as they are described, must be

stomach-turning. Do we have comparable nuisances over here? And if so, who does what about them?

BURROW, H. The Future Control of Abattoirs and Knackeryards. *J. Roy. San. Inst.* 67, 2:95 (Mar.), 1947.

Anent Measuring Knowledge—Our own merit system workers delve into the field of public health nurse selection with some special projects. These are discussed in detail which I found absorbing, for I am one of the dogs they try some of their tests on.

DEMING, D., *et al.* Progress in Merit System Unit Examinations. *Pub. Health Nurs.* 39, 2:73 (Feb.), 1947.

Safe Eating-Out—To promote balanced eating-place sanitation programs in each state; to stimulate adoption of effective state legislation; and to encourage uniform enforcement through legal and educational measures—these are the aims of U.S.P.H.S. restaurant sanitarians.

FUCHS, A. W. Restaurant Sanitation Program of the United States Public Health Service. *Pub. Health Rep.* 62, 8:261 (Feb. 21), 1947.

Finger Pointed at Mice—More about New York's new disease—rickettsialpox. Usually mistaken for atypical chickenpox, it was just called a fever or rash of unknown origin. Rickettsias were isolated from patient's blood and parasites of mice.

GREENBERG, M., *et al.* Rickettsialpox—a Newly Recognized Rickettsial Disease. *J.A.M.A.* 133, 13:901 (Mar. 29), 1947.

Another Reminder to Go Slow—Anaphylactic shocks following injections of typhus (chick-embryo) vaccine are reported. It is recommended that *all*

candidates for chick-embryo vaccines be tested, or questioned, for sensitivity.

HAMPTON, S. F. Anaphylactic Shock in Egg-Sensitive Individuals Following Vaccination with Typhus Vaccine. *J. Lab. & Clin. Med.* 32, 2:109 (Feb.), 1947.

Good News for Epidemiologists—

Two reports on the use of penicillin against scarlet fever agree that it works. Says one, "penicillin therapy resulted in a prompt fall in temperature, a decrease in toxicity, and a decided reduction in the incidence of pyogenic complications and of the carrier state." Says the other "fewer complications followed its use."

HIRSH, H. L., *et al.* Penicillin Therapy in Scarlet Fever. (and) HOHNE, A. L., and BROWN, R. H. Penicillin for Scarlet Fever. *J.A.M.A.* 133, 10:661 (Mar. 8), 1947.

One Tooth Tells—General prevalence of caries, and the proportion of children who have one, or more, carious teeth are closely related. This fact permits of a reliable and rapid method of evaluation for dental preventive programs. A dentist and a clerk can cover a lot of ground in one week.

KNUTSON, J. W., *et al.* Simplified Appraisal of Dental-Health Programs. *Pub. Health Rep.* 62, 12:413 (Mar. 21), 1947.

This Will Discourage You—

Among malnourished patients the decayed-missing-or-filled teeth were only a third of those in a control group of well nourished patients. This finding doesn't do much to aid or comfort those of us who teach that the way to good teeth is via the vitamin-filled dinner pail, does it?

MANN, A. W., *et al.* A Comparison of Dental Caries Activity in Malnourished and Well-Nourished Patients. *J. Am. Dent. A.* 34, 4:244 (Feb. 15), 1947.

Vector Control Is Indicated—

Current scientific opinion about rabies,

psittacosis, and arthropod-borne encephalitis is reviewed to good effect. Did you know that a single anti-rabies vaccination will do for dogs, but cats should get three? Did you know that ducks may have psittacosis? Did you know that equine encephalitis is most common among children under 5? If you are as uninformed as I was in these matters then you will do well to read this paper, too.

MEYER, K. F., and EDDIE, B. Human Virus Infections of Animal Origin. *J.A.M.A.* 133, 12:822 (Mar. 22), 1947.

Forum on the Future—It seems that the (British) National Health Service Act will play hob with local health administrative agencies. In a series of gloomy papers a number of English M.O.H.'s discuss the reorientation of preventive medicine and local government functions which the new program will entail. National social services have a way of coming to life in our country about two decades after they are adopted in England, so you may find something prophetic in this symposium.

THOMAS, E. W. C. The Act and the M.O.H. of a "Minor Authority" (and six related papers). *Pub. Health.* 60, 5:93 (Feb.), 1947.

For Your Own Comfort—In tropical heat, if any clothing must be worn, it should be loose fitting, light weight, expose as much skin as possible, and provide maximum ventilation. Close-fitting, absorbent garments had been suggested but the investigators turned thumbs down. I was sure you'd like to have your layman's opinion confirmed by science.

YAGLOU, C. P., and RAO, M. N. Loose Versus Close-fitting Clothing for Work in "Tropical Heat." *J. Indust. Hyg. & Toxicol.* 29, 2:140 (Mar.), 1947.

ASSOCIATION TO BE REPRESENTED AT
MEETING OF ROYAL SANITARY
INSTITUTE

President Harry S. Mustard, M.D., President-Elect Martha M. Eliot, M.D., and Thomas Dublin, M.D., have been designated as representatives of the Association at the meeting of the Royal Sanitary Institute in Torquay, England, during the week of July 7.

DR. UPDYKE ON STAFF

On March 1 Elaine Updyke, Ph.D., joined the Staff of the Association to work with Pearl Kendrick, M.D., on the pertussis study being conducted under the auspices of the Subcommittee on the Evaluation of Administrative Practices. Dr. Kendrick's pertussis work is being carried on in the Grand Rapids Laboratories of the Michigan State Department of Health, where she is Associate Director of Laboratories in charge of the Western Michigan Division.

A MESSAGE FROM THE CIRCULATION
DEPARTMENT

Because public health workers are notoriously frequent movers hundreds of changes of address are reported to the Circulation Department each month. These changes are recorded promptly. Occasionally, however, a member will write in complaining about non-receipt of *Journals* and report for the first time a new address which has been in effect for several months.

New address notifications received before the 15th of the month will catch the next issue of the *Journal*. Those received between the 15th and the end of the month will be made with the *Journal* published the month after the next. It will assist the Circulation Department and benefit the individual

member if address changes are reported to the Association a month in advance.

Members are also urged to notify their post offices of their new address when they move and to instruct that mail be forwarded.

CLOSING DATE FOR SUBMISSION OF
FELLOWSHIP APPLICATIONS

August 1 will be the last date on which Fellowship applications can be accepted for consideration at the 1947 Annual Meeting in Atlantic City. Eligible members who wish to apply for Fellowship this year are therefore urged to send in their applications as early as possible.

DR. HOWARD M. KLINE OF A.P.H.A.
STAFF ON LEAVE

Howard M. Kline, Ph.D., Bethesda, Md., Technical Secretary of the Subcommittee on Medical Care, American Public Health Association, has been loaned until July 1, 1947, to the President's Scientific Research Board of Washington at the request of the Executive Office of the President. This Board was created by Executive Order in October, 1946, for the purpose of inventorying all research activities in the United States and with special reference to the research which is being conducted within the federal establishment and that which is being conducted outside the federal establishment with federal funds.

Dr. Kline will direct the survey of medical research and conduct special studies incident thereto.

During his leave of absence the staff of the Subcommittee on Medical Care is being guided by Milton Terris, M.D., M.P.H., Medical Associate of the Subcommittee, under the direction of Joseph W. Mountin, M.D., *Chairman*.

EMPLOYMENT SERVICE

The following pages present information for those seeking qualified public health personnel and for those seeking positions in public health.

This is a service of the Association conducted without expense to the employer or employee.

Address all correspondence to the Employment Service, A.P.H.A., 1790 Broadway, New York 19, N. Y., unless otherwise specified.

NEWS FROM THE FIELD

NATIONAL HEALTH COUNCIL RESOLUTION FOR LOCAL HEALTH UNITS

The annual meeting of the National Health Council held in New York City on March 21 adopted the following resolution endorsing the general aim of local health units:

Because coverage of every community of our Nation by the services of an efficient and economical local health department is essential for further development and protection of the health of our people through voluntary as well as official agencies, be it

RESOLVED by the Delegates of the National Health Council that early extension of local health departments with full-time professionally qualified health officers and appropriate associate personnel adequate to the need of all our population be a major concern of the Council; and be it further

RESOLVED that the member agencies of the National Health Council be urged to encourage their state and local organizations to discover the extent of present inadequacy of local health services and take an active part in efforts to secure local health units suitable for each jurisdiction of local government.

Dr. Haven Emerson, Chairman of the Subcommittee on Local Health Units of the American Public Health Association, was the principal speaker at the luncheon meeting. He challenged his audience to action on the basic deficiency in the national health program, which, if uncorrected, would make impossible the fullest realization of the separate goals of the member agencies. He reminded them of the fact that one-third of the population of the United States is without full-time local health service, that the average per capita expenditure for such service is only 61 cents, although one dollar is considered necessary for even minimum service, and that the chief obstacle in overcom-

ing current deficiencies in service is the unsuitability of the 155,000 units of local government for providing health protective services. He urged the Council members to become active in reducing current health jurisdictions to about 1,200 county or multi-county health districts. Through these, the special cancer, tuberculosis, social hygiene, and other programs may be made really effective. Without such a basic tax-supported public health structure many current activities of specialized voluntary agencies are wasteful and ineffective.

MASSACHUSETTS HAS NEW BLOOD PROCESSING LABORATORY

On March 26 the Massachusetts State Department of Health dedicated a new Blood Processing Laboratory at Forest Hills. Geoffrey Edsall, M.D., is Director of the Division of Biologic Laboratories.

THE ARMY FORMS A VENEREAL DISEASE CONTROL COUNCIL

The March, 1947, issue of *The Bulletin* of the U. S. Army Medical Department carries news that should be of interest to everyone concerned with the control of venereal disease. The War Department, as a result of its experiences during the war, recognized the fact that venereal diseases could not be controlled entirely through the efforts of the surgeon of a command.

According to the report carried in the above mentioned bulletin, the Army is preparing to meet with this deficiency through the formation of the War Department Venereal Disease Control Council, which will consist of the Director of Personnel Administration, Chief of the Chaplains, Chief of Special Services, Provost Marshal General, Sur-

geon General, Chief of the Bureau of Public Relations, and representatives of the Secretaries of War, the Army Air Forces, and the Army Ground Forces.

According to the article, the duties of the Council will be quite widespread going into the multitudinous problems involved in the control of venereal disease. The assistance of other official and nonofficial agencies is to be sought.

NURSE RECRUITMENT PROGRAM

The American Hospital Association (18 E. Division St., Chicago 10) has initiated and is sponsoring a national Student Nurse Recruitment Program. Its goal is at least 45,000 student nurses in the nation's 1,300 nursing schools in 1947. This is 50 per cent more student nurses than were registered in 1946.

The Hospital Association has appropriated \$10,000 toward financing the program. The Advertising Council, Inc., is also giving active assistance as well as are organizations and associations interested in the nurse shortage. A special staff has been assembled at the Hospital Association headquarters to assist and stimulate development of local Student Nurse Recruitment programs.

A survey by the American Hospital Association showed that on February 15, more than 33,000 hospital beds throughout the country were closed, chiefly because of the shortage of nurses. Further, more hospitals report growing waiting lists for admissions for care of non-emergency conditions.

MINNESOTA PUBLIC HEALTH CONFERENCE ORGANIZED

In January, the Minnesota Public Health Conference was organized by a group of persons professionally interested in public health. Active membership is made up of those persons engaged in public health work in Minnesota who are members or Fellows of

the American Public Health Association, or eligible to such membership. Provision is also made for corporate membership, and three classes of non-voting membership—associate, honorary, and sustaining. Future affiliation with the American Public Health Association is planned.

The new organization is an outgrowth of the 40 year old Minnesota State Sanitary Conference which has been relatively inactive in recent years.

The officers of the new Conference are:

President: Floyd Feldman, M.D., Health Officer, Rochester

Vice-Presidents: A. E. Amundsen, M.D., Health Officer, Little Falls; J. Lawrence McLeod, M.D., Health Officer, Grand Rapids

Treasurer: Charles G. Sheppard, M.D., Health Officer, Hutchinson

Secretary: Donald A. Dukelow, M.D., Secretary, Health Division, Minneapolis Council of Social Agencies

INDIANA PUBLIC HEALTH ASSOCIATION

Late in 1946 a group of Indiana public health workers met to organize the Indiana Public Health Association. It is planned that it shall be eligible for affiliation with the American Public Health Association. The first annual meeting will be held at some time in the spring of 1947.

Officers of the new Association are:

President: Murray A. Auerbach, Executive Secretary, Indiana Tuberculosis Association

Vice-President: Walter L. Portteus, M.D., President, Indiana Health Officers' Association

Secretary: Lucretia Saunders, Health Education Consultant, Indiana State Department of Health

Treasurer: Cecelia Schuck, Ph.D., Director of Nutrition, Purdue University

SOCIAL ASPECTS OF ATOMIC BOMB AWARD

The Society for the Psychological Study of Social Issues of the American Psychological Association announces an award of a \$1,000 United States Government Bond to encourage research

on the social aspects of the atomic bomb. Known as the Edward L. Bernays Atomic Energy Award, it will be given in 1947 to the individual or group contributing the best action-related research in the field of the social implications of atomic energy. The committee of judges includes six university professors whose chairman is Dr. David Krech, Swarthmore College, Swarthmore, Pennsylvania. All communications should be addressed to him and all entries must be in his hands, in duplicate, not later than November 1, 1947.

NORTH CAROLINA MEDICAL CARE COMMISSION

The *Charlotte* (N. C.) *News* for February 11, 1947 is a 52 page issue whose title page reads "Better Health for North Carolinians: A factual survey of state health needs." This has articles by many public health experts, among them State Health Officer Carl V. Reynolds, M.D.; Medical Care Commission Executive Secretary, John A. Ferrell, M.D., and other members; I. G. Green, M.D., President of the Good Health Association; Selz C. Mayo, Rural Sociologist of the North Carolina State College, and many others. Included also is the five-year hospital plan of the Medical Care Commission by which North Carolina's 20,000 present hospital beds would be increased by about one-half.

Among other material prepared by or describing the work of the North Carolina Medical Care Commission is a booklet of endorsements of the Commission's health plan. Copies have also been received of the health bills being considered by the North Carolina legislature. These bills provide that the Commission shall allocate state funds to local governments for the construction and maintenance of hospitals, license public and voluntary hospitals, and administer a loan fund for medical, dental,

nursing, or pharmacy students who will practise in a rural area of the state for 4 years after being licensed.

Also received from the Commission is a pamphlet of its public relations branch, the North Carolina Good Health Association. This is entitled "North Carolina's No. 1 Need: Good Health." It lists 14 unfavorable health situations in the state such as its high infant and maternal mortality rates, its shortage both of practising physicians and of hospital beds, its high percentage of draft rejections, and high percentage of "repeaters" in school grades. Then are listed the things to be done, the Commission's plan for accomplishing these things, what they will cost and what their benefits will be.

The Medical Care Commission has also published *Hospital and Medical Care for all our People*, which is a republication of the various subcommittee reports of the Governor's Hospital and Medical Care Commission created in 1944 and operating until the permanent Medical Care Commission was created late in 1945. All data of these reports have been revised as of February, 1947. State Health Commissioner Reynolds has said that these committee reports are "the most comprehensive, accurate, and informing review of health conditions ever made in the history of North Carolina—and probably the best ever yet made for any Southern State."

PRESIDENT URGES U. S. PARTICIPATION IN WORLD HEALTH ORGANIZATION

On March 21 President Truman sent to the United States Congress, a proposed joint resolution urging participation in the World Health Organization. He strongly recommended early consideration, pointing out that the United States signature to the constitution in July, 1946, was contingent on Congressional endorsement.

The World Health Organization becomes a permanent body upon legisla-

tive endorsement by 26 states. Currently, eight countries have ratified the proposed constitution adopted by the World Health Conference of 1946, the latest to ratify being the government of Switzerland.

Last November the WHO took over from the UNRRA the functions of the International Sanitary Conventions on collection and dissemination of information on pestilential diseases. This year all other UNRRA health functions have been turned over, together with a fund of one and a half million dollars. These include a malaria control program in Europe; a tuberculosis program, which includes mobile x-ray units for case finding; training fellowships for health technicians; "the Ethiopian project," for training health leaders in Ethiopia in disease control; and a program of aiding government by missions of public health experts.

U.S.S.R. APPOINTS MINISTER OF HEALTH FOR SOVIET UNION

Colonel General Yefim Ivanovitch Smirnov, D.M.Sc., who was formerly Chief of the Medical Division of the Ministry of Defense and Professor in Leningrad of Military Medicine, age 45, has been appointed Minister of Health of the Soviet Union. According to reports, this is the first time this post has been held by a person wholly the product of the Soviet system. His appointment replaced Dr. Mitervec as Minister of Health on February 17.

U. S. SENATE HEARINGS ON PROPOSED CABINET STATUS FOR PUBLIC HEALTH

Hearings in Washington before the Senate Committee on Expenditures in the Executive Departments, Hon. George B. Aiken of Vermont, Chairman, began on March 17 with special reference to the Taft-Fulbright Bill (S. 140) and to the Aiken Bill (S. 712). Among those heard were Watson Miller, the

Federal Security Administrator, who supported S. 712, and Ernest L. Stebbins, M.D., of Baltimore, Co-Chairman of a Committee on a Federal Department of Health, Education and Security sponsored by the American Council on Education and the National Social Welfare Assembly, also supporting the principles of a simplified bill like S. 712. The Conference of State and Territorial Health Officers was represented by Dr. Vlado A. Getting of Massachusetts, offering further support for S. 712. Organized medicine was represented by members of the Board of Trustees of the American Medical Association, who argued that it was unwise for public health to be associated with any other federal agencies and supporting a goal of a separate Department of Health with Cabinet status.

The American Public Health Association was represented at the hearings on March 24 by Reginald M. Atwater, M.D., Executive Secretary, who at the direction of the Executive Board of the Association pointed out that our organized facilities still lag far behind our potential ability to improve the public health, and that a large number of the social evils which we have been fighting in this country have their roots in bad health, and that Congress has wisely recognized this relationship by writing into the original Social Security Act provisions for making the federal services for health much more effective. In the long run, he said, it may easily be that these investments in health will represent some of the most significant features of our social security. After nearly twelve years' experience with the operation of the Social Security Act and such laws as Public Law 410, it is manifest that a structure of Cabinet rank is an essential to the importance of the task at the federal level. The Association recommended the immediate establishment of a Cabinet Department of Health, Education and Security to

be set up in a simple and flexible manner, allowing wide latitude for the adaptation of administrative structure to scientific advance.

Dr. Atwater said that, in the opinion of the Association, the present scope and character of the Federal Security Agency clearly indicates that this is the agency of the Federal Government which should have departmental status and a permanent place in the Cabinet. This seemed true whether the scope and character are measured in terms of federal financial involvement, the number of persons concerned, or in the importance of health, education and welfare.

It seems appropriate that the agencies dealing with health, education and security at the federal level should be thoroughly coördinated because corresponding agencies at the local and state levels are so generally separate and distinct. A first rate example of coördination in the proposed federal department would be useful.

It was recommended that the existing Federal Security Agency be converted to an executive Department by transferring the powers and duties of the Agency and its administrator to the new Department and to its Secretary. The matter of transferring any additional functions or units of other governmental agencies performing related services should be left for subsequent legislative action. The Association believes that the functional operating divisions or other units of the Department should be headed by career officers with high professional and administrative competence in their particular fields. These latter positions should be non-political in character.

It was recommended that the legislation should carry an expression of intent to insure freedom of state and local agencies, public or voluntary. Of equal importance, however, it should be clear that this legislation does not interfere with the administration of federal funds

in an orderly and non-political manner as provided, for example, by the 1939 amendments to Title V of the Social Security Act. Early passage of Senate Bill 712 was recommended as the best means of accomplishing these purposes.

The Association recommended against the provisions of Senate Bill 140 in so far as it divides the proposed Department into three separate and distinct divisions, each headed by an Under Secretary, because this would tend to separate the functions of health, education and security instead of promoting their coördination. It was pointed out that such programs as school health, vocational rehabilitation, and the care of crippled children certainly represent a desirable interlocking of health, education and security interests.

Dr. Atwater said that the professional society of public health workers finds itself of the opinion that it is unwise to provide as in S. 140 that the Under Secretary for Health shall be a licensed physician. It is the Association's opinion that under the American form of government the Assistant or Under Secretaries generally represent broad public interest and policy determination, while the Bureau Chief is a technical and professional person. It is believed that these functions would be confused if combined in a single individual. In the Division of Health as provided in S. 140, further administrative difficulty might readily arise from placing a technical person whose qualifications are only that he must be a licensed physician in a position above such a highly trained and specialized professional person as the Surgeon General of the United States Public Health Service.

In summary, the American Public Health Association supported the idea of Cabinet status for the Federal Security Agency in approximately its present form and registered itself as in favor of Senate Bill 712 as an acceptable means of obtaining this end.

DR. MCGAVRAN APPOINTED DEAN AT
UNIVERSITY OF NORTH CAROLINA

Edward G. McGavran, M.D., M.P.H., now Professor of Public Health and Preventive Medicine at the University of Kansas School of Medicine, Kansas City, has been appointed Dean of the School of Public Health at the University of North Carolina, Chapel Hill. Dr. McGavran succeeds the late Milton J. Rosenau, M. D., who died April 9, 1946.

Dr. McGavran is a graduate of the Harvard Medical School and of the Harvard School of Public Health. He has served in Michigan, West Virginia, and St. Louis County, Missouri, before assuming his present duties in 1946. Dr. McGavran is a member of the Executive Board of the American Public Health Association.

NEW BOLIVIAN PUBLIC HEALTH
ASSOCIATION

Announcement has been received of the organization as of January 1, 1947, of the Bolivian Public Health Association. It is described as an organization made up of members of those professions in Bolivia that are related to preventive medicine, hygiene, and sanitation, for the purpose of improving the sanitary conditions of the country. Its officers are:

President: Dr. Nemesio Torres-Muñoz

Vice-President: Dr. Israel Zegarra

Secretary-General: Dr. Miguel Lévy

Treasurer: Dr. César Moscosco

MUNICIPAL CONSTRUCTION PLANS
EMPHASIZE SANITATION PROJECTS

Evidence of the widespread municipal interest in structures and installations contributing to the promotion of public health can be found in the Federal Works Agency Advance Planning Program as of December 31, 1946.

The 1,776 projects representing 31.3 per cent of the total dollar value of completed design plans are for sewer,

water and sanitation facilities; 2,226 projects representing 24.3 per cent of the total dollar value of project plans now under design are in the same category. These proposed improvements occupy first place in both number of projects and dollar value.

State sanitary engineers have been active in assisting municipalities in the procurement of F.W.A. assistance in the preparation of such plans.

Other types of projects aiding public health include 138 completed plans and 206 in design for hospitals and health facilities.

FRENCH PUBLIC HEALTH HONOR
TO DR. HENNESSY

Harold R. Hennessy, M.D., C.P.H., Assistant Secretary, Council on Industrial Health, American Medical Association, Chicago, Ill., has recently been notified that the President of the French Republic, on the recommendation of the Minister of Public Health, has issued a decree pronouncing him "Chevalier de l'Ordre de la Sante Publique." Dr. Hennessy, a Colonel in the Medical Reserve Corps, participated in the allied planning for the public health program of France assisting in the reestablishment of the French public health system, particularly the problems associated with displaced persons, refugees and returning French prisoners of war.

CHEST X-RAY PROGRAM IN NEW ORLEANS

February was federal month in New Orleans. The personnel of 71 federal agencies located in New Orleans participated in the mass chest x-ray program sponsored by the New Orleans Health Department and the New Orleans Tuberculosis Association. In spite of cold and rain, in spite of the Carnival season and Mardi Gras, more than 8,000 persons had chest x-rays. Preparatory educational meetings were conducted in many of the agencies. In

this survey, as in other mass x-ray surveys in New Orleans, the individual x-rayed was informed by letter of the result. This program was conducted by Robert L. Smith, M.D., Director of Tuberculosis Control and Milton E. Kossack, Director of Health Education for the Health Department; and by Miss Maretta Rocquet for the Tuberculosis Association.

KANSAS PUBLIC HEALTH ASSOCIATION ANNUAL MEETING TO BE MAY 27-28

The annual meeting of the Kansas Public Health Association will be held May 27-28, with headquarters in the Allis Hotel, Wichita. Charles A. Hunter, Ph.D., President of the Association, announces that C. H. Kinman, M.D., State Epidemiologist, will be the honor guest.

VIRGIN ISLANDS EXTENDS HEALTH SERVICES

Following the extension of federal aid to the Virgin Islands for Maternal and Child Health and Crippled Children's programs, John S. Moorehead, M.D., M.P.H., has been appointed Director of these two services in the Islands. The following additions have also been made to the staff of the St. Thomas Department of Health:

Peter Sabatelle, M.D., Orthopedic Surgeon
Laura L. Moorhead, R.N., Director of Public Health Nurses
Viola Collins, R.N., Maternal and Child Health Nurse
Magdalane Clark Wainright, R.N., Public Health Nurse

ADVERTISING COUNCIL'S TUBERCULOSIS PROGRAM

The May *Bulletin* of the National Tuberculosis Association announces definite plans for a year-round educational campaign on tuberculosis by the Advertising Council. In coöperation with the National Tuberculosis Association, its affiliated associations, and the U. S. Public Health Service, the

campaign will be launched in the fall. It will use the channels of public education available to advertising—radio, newspapers, magazines, including farm, trade, and professional journals, posters, etc. The main emphasis of the campaign will be the necessity of periodic chest x-rays for the entire adult population.

The Advertising Council was organized in 1942 to bring the combined services of advertising agencies to the various volunteer war efforts, bond selling, enlistment, community chest, and many others. It is a "non-profit organization representing all phases of advertising, dedicated to the use of advertising in the public services." It is currently sponsoring campaigns for the National Safety Council, the Federal Housing Administration, and the World Trade Foundation, among others.

DR. WEST RESIGNS AS PRESIDENT-ELECT OF AMA

On April 1 Olin M. West, M.D., resigned as President-Elect of the American Medical Association because of ill health. Dr. West, who was formerly Tennessee State Health Officer, served for many years as Secretary and General Manager of the American Medical Association, a position from which he retired in 1945 at the age of 70. He was to have been inaugurated as President at the 1947 annual session.

Dr. West is being succeeded as President-Elect by Edward L. Bortz, M.D., of Philadelphia. Dr. Bortz, who is Associate Professor of Medicine at the University of Pennsylvania Graduate School of Medicine, will become President at the Annual and Centennial meeting in Atlantic City, June 9-13.

NATIONAL NURSING COUNCIL STUDIES NURSING JOBS

Under a grant of \$28,000 from the Carnegie Corporation, the National Nursing Council is making an intensive

study of the nurse's job and the necessary changes in education required to prepare her for it. The study will be preceded by a week long nurses' workshop whose aim is to define the rôle of the registered nurse. The workshop will bring together nurses from all over the country representing public health, industrial nursing, and hospital care, as well as consultants from medicine, social work, and allied fields. The study, designed to find an answer to the nurse shortage, will focus on the problem of how a basic professional nursing school should be organized, administered, and financially supported to prepare its graduates adequately to meet community needs. Dr. Esther Lucile Brown, who is director of the Department of Studies in the Professions of the Russell Sage Foundation, will conduct the study.

DR. BAUMGARTNER COMPLETES TEN YEARS OF CHILD HEALTH WORK

On March 25 in New York a group of organizations and individuals gathered for luncheon. They were there to take note that Leona Baumgartner, M.D., has completed ten years as Director of the New York City Department of Health's Bureau of Child Hygiene. The sponsoring organizations were a baker's dozen; the individuals some 300, representing a variety of medical and lay approaches to the problem of child health.

C.-E. A. Winslow, Dr.P.H., summarizing the ten years of progress, pointed out that if the same infant rate had prevailed in 1946 as in 1908 when the Bureau of Child Hygiene was first organized by the late Josephine S. Baker, M.D., 17,000 babies would have died. Actually only 4,000 did.

Dr. Baumgartner herself talked of the things still to be done—research into the cause and prevention of stillbirths of which there are annually 10,000 in New York City; universal care for pre-

mature births of the quality that only best doctors and hospitals now give; reduction of the infant mortality rates in some of the underprivileged areas of the city; "the rate is as high in Harlem as in some of the poorest southern states."

Donovan J. McCune, M.D., Chairman of the Health Section of the Citizens' Committee on Children, presented a report of his committee, "Citizens Look at Their Services for Children."

NEW ENGLAND HEALTH INSTITUTE

The first Post-War Institute will be held at the University of New Hampshire June 16-18. There will be nine section and joint sessions, a luncheon, a banquet, and a dance. Make reservations through the Business Office of the University, Durham, N. H.

TWO NEW CARE PACKAGES

CARE (Cooperative for American Remittances to Europe) announces three new \$10 packages. The CARE woolen package contains 3½ yards of all woolen cloth. Heavy cotton lining, thread, buttons, needles, and thimble are included.

The CARE blanket package includes two all wool blankets, two pairs of heels and soles, a pair of scissors, an assortment of pins, needles, threads, yarns, and a thimble and comb.

The CARE cotton package contains 4 yards each of white broadcloth, of pink or blue broadcloth, and of printed dress material; 2½ yards each of printed shirting and navy drill, as well as thread, needles, scissors and thimble. Care, 50 Broad Street, New York 4.

PERSONALS

Central States

D. C. BARRETT, M.D., M.P.H.,† has been appointed Director of the Bureau of Local Health Administration in the Indiana State Department of Health.

GLADYS KRAUSE has resigned her position as Director of the Division of Vital Statistics in Nebraska. CLAIR L. CHISM is the new registrar.

HOWARD E. LIND,† formerly Research Bacteriologist with the Dow Chemical Co., Midland, Mich., has resigned to accept a position as Director of the Sias Laboratories, Brooks Hospital, a diagnostic research and consultative hospital in Brookline, Mass.

ELTA MAE MAST† has recently been appointed to serve as liaison officer between the Health and Physical Education Division of the Office of the Superintendent of Public Instruction and the Division of Public Health Education of the Department of Public Health, State of Illinois.

LYDIA REITZ† has been appointed Educational Director for the Division of Public Health Nursing of the Illinois State Department of Public Health.

LEONARD SCHUMAN, M.D.,† has been appointed to the position of Chief of the Division of Venereal Disease Control in the Department of Public Health, Illinois. Dr. Schuman had previously served as District Health Superintendent with headquarters at Woodstock, Ill., and as Assistant Chief of the Division of Local Health Administration in the Department.

CECIL A. Z. SHARP, M.D.,* has accepted the positions of Health Officer of the St. Louis County Health Department, Clayton, Mo., and Assistant Professor of Preventive Medicine at the Medical School of Washington University, St. Louis, Mo.

GEORGE A. SHERMAN, M.D., Director of the Michigan State Health Department, Bureau of Tuberculosis Control since 1941, has resigned to enter private practice as of March 1, 1947.

FRED O. TONNEY, M.D.,† formerly

District State Health Officer for the Northern Illinois area, was appointed City-County Health Officer at Mansfield, Richland County, Ohio, effective January 1.

DONALD W. TRIPODI, M.D., has been appointed by the Local Board of Health as Health Officer of the Alexander-Pulaski Bi-County Health Department (Illinois) effective February 1, 1947. The Alexander-Pulaski Bi-County Health Department with headquarters at Cairo, was permanently established by popular vote on November 5, 1946, when 17 counties voted in favor of county or multiple county health departments. Besides Dr. Tripodi, two other new members were appointed to join the staff, EMMA JENNINGS, R.N., has been appointed as Public Health Nurse, and RALPH GIBSON, Cairo, as Sanitarian.

BEN L. WILLIAMSON* has been appointed Director of the Division of Sanitation, Kansas State Board of Health. He is currently Assistant Engineer in the Iowa State Health Department. DWIGHT METZLER,† Assistant Director of the Sanitation Division, has been appointed Acting Director until the arrival in Kansas of Mr. Williamson.

EARL J. WINTERS, formerly chief technician of the x-ray service of the Cuyahoga County Tuberculosis Clinic, Cleveland, O., has been appointed field assistant of the New York Tuberculosis and Health Association's chest x-ray service. Mr. Winters will schedule the association's mass x-ray projects and will emphasize extension of this work among business and industrial concerns in Manhattan, New York City.

JOHN S. WISELY, M.D., has resigned his position with the Molly Stark Sanatorium, Canton, Ohio, to accept

* Fellow, A.P.H.A.

† Member, A.P.H.A.

the position as Director of Tuberculosis Control with the Cattaraugus County Department of Health, Olean, N. Y., and Superintendent of Rocky Crest Sanatorium.

Eastern States

ABRAHAM Z. BARHASH, M.D., New York, has been appointed Director of the Division of Community Clinics of the National Committee for Mental Hygiene, succeeding MILTON E. KIRKPATRICK, M.D.

MARGUERITE M. FUREY, R.N., has been appointed by the National Society for the Prevention of Blindness, New York, N. Y., as Consultant in Nursing Activities.

APPOINTMENTS IN THE MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH:

EUGENE R. SULLIVAN, M.D., has been appointed an Assistant Director, Division of Biologic Laboratories. Dr. Sullivan served 3 years overseas as Chief of Laboratories, 6th General Hospital, as consultant on blood and blood transfusions for the North African and Mediterranean theatres of operation. He was awarded the U. S. Legion of Merit and the Order of the Crown of Italy, Degree of Knight-Commander.

BARBARA FORD CARTER, M.D., former House Officer and Assistant Resident, Boston City Hospital, has been appointed Assistant District Health Officer of the North Metropolitan District.

MARTHA HOWARD FALES, B.A.,† formerly dental health consultant, Michigan Department of Health, has joined the staff of the Division of Dental Health, as Public Health Dental Hygiene Supervisor.

SALVATORE R. TRAINA, M.D.,† former Command Surgeon of the 7th

Air Service Area Command in Tokyo, is now Physician in charge of the mobile unit of the State Blood Donor Program, Division of Biologic Laboratories.

JULIAN M. KARASOFF, D.V.M., has been appointed Veterinary Food Inspector in the Division of Food and Drugs. Prior to his appointment, Dr. Karasoff practised privately as a veterinarian.

MARY STEICHEN, M.D., M.S.P.H.,* New York City, has been appointed Acting Medical Director of the Planned Parenthood Federation of America, Inc.

W. T. S. THORP, V.M.D.,† Professor of Veterinary Science at Penn State College, State College, Pa., has been appointed to the staff of the National Institute of Health, Bethesda, Md., to head a veterinary section in the Pathology Division.

STAFFORD L. WARREN, M.D., Professor of Radiology at the University of Rochester, N. Y., School of Medicine and Dentistry, and during the war Chief of the Medical Division for the entire atomic bomb project under the Manhattan District, has been appointed Dean and Professor of Biophysics of the new Medical School on the Los Angeles campus of the University of California. He will supervise plans for the medical school buildings and university hospital of 500 beds to be built on the Los Angeles campus, and assemble a faculty and staff for the new institution. The State of California already has appropriated \$7,000,000 for the project and additional funds have been requested from the current Legislature.

Southern States

PAUL C. CAMPBELL, JR.,† Surgeon, U. S. Public Health Service, has been appointed Chief of the Office of Dermatology, Industrial Hygiene

* Fellow, A.P.H.A.

† Member, A.P.H.A.

Division, U. S. Public Health Service, Federal Security Agency. Dr. Campbell succeeds LOUIS SCHWARTZ, M.D.,* who will retire on July 4 after 41 years of service.

SURGEON GEN. HUGH S. CUMMING,* (retired), U. S. Public Health Service, Washington, D. C., was elected director emeritus, at the 12th Pan American Sanitary Conference in Caracas, Venezuela, of the Pan American Sanitary Bureau after 26 years of active service as director. Gen. Cumming retired as director of the bureau on January 21 and FRED L. SOPER, M.D.,* of the Rockefeller Foundation, New York, assumed the office.

PAUL HANEY, M.S.E.,* has begun his new work as Professor of Sanitary Engineering at the University of North Carolina. During the past 15 years he has been with the Kansas State Board of Health, since 1942 as Director and Chief Engineer of the Division of Sanitation.

MERLE P. MOON, PH.D.,* has resigned his position at the University of Missouri to assume a position with the Kentucky State Medical Association in Louisville which includes responsibility as Associate Editor of the State Medical Journal.

APPOINTMENTS IN THE NEW ORLEANS HEALTH DEPARTMENT:

SIM B. SHATTUCK† has been appointed Acting Director of Bureau of Vital Records. He was formerly with Louisiana State Health Department as Chief of Registration and Records.

LILLIAN S. HAWES, R.N., has been appointed Education Director, Bureau of Public Health Nursing. Miss Hawes most recently was with the War Relocation Authority as

Chief Nurse of Nursing Service, Manzanor, Calif.

OLIVIA SMYTHE, R.N.,† has been appointed Consultant on Maternal and Child Health, Bureau of Public Health Nursing. Miss Smythe was formerly with the U. S. Army Nurse Corps—126 Station Hospital, Southwest Pacific.

JAMES G. FAUSTINA† has been appointed Supervisor of Health Education. He was formerly Health Education Consultant, U. S. Public Health Service.

ANDREW P. SACKETT, M.D., Medical Officer in charge of Kanawha Valley Medical Center (VD), South Charleston, W. Va., has been appointed Acting Director of the Bureau of Venereal Disease Control in the State Health Department. Dr. Sackett will continue as Medical Officer in charge of the rapid treatment center in South Charleston.

LOUIS SCHWARTZ, M.D.,* Chief, Office of Dermatology, Industrial Hygiene Division, U. S. Public Health Service, will retire from the Service on his 64th birthday, July 4, 1947. Dr. Schwartz has been serving the public for more than 41 years. He has been instrumental in focusing attention on dermatological problems in industry.

CHARLES P. STEVICK, M.D.,† former Director of the Bureau of Vital Statistics in North Carolina, has again assumed this position. Dr. Stevick will also resume the duties of registration executive.

MELVILLE A. TAFF, JR.,† Registrar in Louisiana, has joined the staff of the National Office of Vital Statistics. Mr. Taff will be a member of the Latin American Consulting Staff and will be in the States for orientation about 2 months before leaving the country.

RAYMOND A. VONDERLEHR, M.D.,* has been appointed Medical Officer in

* Fellow, A.P.H.A.

† Member, A.P.H.A.

charge of the Communicable Disease Center of the U. S. Public Health Service at Atlanta, Ga. Until recently he was in charge of District 6 of the Service with headquarters in San Juan, Puerto Rico.

CLARENDON B. WOODS, M.D., Washington, D. C., has been appointed Health Officer for Hampton and Colleton Counties, Ga., with headquarters in Walterboro.

Western States

J. P. CLEARY, M.D.,† has been appointed Director of the Division of School Hygiene, Portland, Ore.

ELEANOR MATSUMATO, formerly with the Farm Security Administration in Hilo, has been appointed nutritionist for rural Oahu by the Hawaii Territorial Board of Health.

ROBERT J. M. HORTON, M.D., M.P.H.,† has been appointed full-time Medical Health Officer for Kauai County, H. I. Dr. Horton, recently discharged from the U. S. Army Medical Corps, has just completed his public health work at the Harvard School of Public Health.

Canada

JOHN LLEWELLYN LITTLE, M.D., of the staff of the Directorate, Health Insurance Studies, Department of National Health and Welfare, Ottawa, Canada, was a recent visitor at a meeting in New York of the A.P.H.A. Subcommittee on Medical Care.

Foreign

MARIO CIOLLI, M.D., of Havana, Cuba, has been appointed Director of the Division of Pan American Medical and Health Relations of the Finlay Institute by Ramon Grau San Martin, President of the Republic of Cuba.

ARTHUR MASSEY, C.B.E., M.D.,* has

resigned as Medical Officer of Health and School Medical Officer of Coventry, England, to become Chief Medical Officer to the Ministry of National Insurance, whose office is at 6, Carlton House Terrace, London, S. W. 1.

Puerto Rico

EDUARDO GARRIDO-MORALES, M.D.,* San Juan, former Health Commissioner of Puerto Rico, has been appointed to act as local director for the Hospital Facilities Division, U. S. Public Health Service, and to act also as consultant to antivenereal and antituberculosis programs that are being conducted in the Island with federal and insular funds.

Death

GEORGE T. PARKINSON, M.D., Health Officer, South Central District Health Unit, Twin Falls, Idaho, died March 1 of coronary occlusion.

CONFERENCES AND DATES

American College of Hospital Administrators: Third Fellows Seminar. University of Washington, Seattle, Wash. May 5-9.

Third New England Institute for Hospital Administrators. Brown University, Providence, R. I. June 19-28.

Maritime Institute in Hospital Administration. St. John, New Brunswick, Canada. June.

Third Western Institute for Hospital Administrators. Stanford University, Palo Alto, Calif. August.

Fifteenth Chicago Institute for Hospital Administrators. University of Chicago, Chicago, Ill. September 2-12.

Annual ACHA Convocation and General Assembly of Membership. St. Louis, Mo. September 21-22.

American Congress of Physical Medicine. 25th Annual Scientific and Clinical Session. Hotel Radisson, Minneapolis, Minn. September 2-6.

American Dental Association. Annual Meeting. Boston, Mass. August 4-8.

American Dietetic Association. Philadelphia, Pa. October 13-17.

American Hospital Association. Annual Convention. St. Louis, Mo. September 22-25.

What Is Health Education?

A Symposium Prepared at the Request of the Editorial Board

W. W. BAUER, M.D., F.A.P.H.A.

American Medical Association, Chicago, Ill.

HEALTH education is the sum total of all our experiences and motivations which add to health knowledge or influence health behavior.

Health education is much bigger and broader than what we commonly think of when this term is used. Teaching in the schools about health is health education. So also is some of the indiscriminate radio listening done at home. Living in the home or school constitutes health education for better or for worse. If school environment, either physical or psychological, clashes with theoretical teaching then we may have health education of a negative sort.

Health education includes a great deal of influence derived from commercial sources. The high place held by citrus fruits in our diet is due only in part to an appreciation of their dietary value and much more to the initiative, enterprise, and competitive zest of the fruit growers of California, Arizona, Texas, and Florida. In the same way, the acceptance of coffee as a national drink and the tremendous use of soft drinks is a reflection of our health education ex-

perience as a whole. Whereas the use of citrus fruits, for example, indicates a positive balance of forces, the excessive use of coffee and the widespread abuse of tobacco represent a negative balance in the forces which determine the resultant conduct of the individual.

Health education has two principal components: information and motivation. Information may be all true, part true, part false, or all false, according to Donald B. Armstrong's classification in his article "Can It Now Be Told?"* Motivation may be positive or negative and this may depend in part on information. Mere giving of information or its passive acceptance is only a part of health education because it does not inspire conduct and, therefore, leaves the situation essentially unchanged. Conduct is inspired by the urge to do something. This urge may be based on fear, ambition, jealousy, determination, malice or any combination of these or other emotional drives. In health education, as in religion, there is no action unless motivation takes place.

* *Health & Phys. Educ.*, VI, 6 (June), 1935.

HERMAN N. BUNDESEN, M.D., F.A.P.H.A.

President, Board of Health, Chicago, Ill.

What is health education? To my way of thinking, health education is a matter of teaching the community and the individual how to guard against health hazards. It is up to the health department to protect public health just as it is up to the police to insure public safety, and up to the home, church, and school to set good standards of behavior.

In Chicago, we provide among other facilities laboratory services, infant welfare clinics, treatment and isolation for communicable diseases, and school hygiene service. The value of these facilities to the public depends on the use the public is taught to make of them.

We use the direct approach; we frankly advertise Health Department services. With 3,500,000 people to educate, we follow the example of the successful business enterprise with a product to sell.

Our "product" is public health service. We publish simple, graphic material about every phase of public health and build special publicity campaigns to combat new health problems as they arise. Over the years, the public attention we have focused on infant welfare has been an important factor in maintaining our low infant mortality rate. The backbone of this campaign has been the widespread distribution of accurate, detailed, but easy-to-read literature.

In a health education drive against

diphtheria, the entire health department staff took to the field for a city-wide canvass of families with preschool children who had not received toxoid inoculations.

A current example of our education tactics is our VD control program. In VD, we had a health problem the public had long preferred to ignore. Led by the *Chicago Tribune*, the press helped us launch our campaign in 1937.

Last February — "VD Control Month" by proclamation of the Mayor — our public information drive co-sponsored by the Chicago Junior Association of Commerce included car card advertising and radio as well as newspaper coverage. The 50,000 VD tabloids handed out to Loop shoppers and workers as a publicity stunt were pocketed readily whereas twelve years ago, few people would have accepted them.

During the war, we developed an education program for the city's 8,000 liquor licensees to deal with the promiscuous encounters leading to VD which were taking place in taverns. Not only did the owners cooperate, they underwrote the printing and distribution of 3,000,000 matchbooks with VD control copy.

These few illustrations represent the kind of health education we are doing in Chicago and the kind we are finding successful.

MARY P. CONNOLLY, F.A.P.H.A.

School of Public Health, University of Michigan, Ann Arbor, Mich.

Health education is that process by which persons become aware of health needs and practices which they may establish to meet these needs. Certain

of these practices are dependent upon facilities.

Who is responsible for health education? The physician in his office when

he indicates a way of life to a patient; the dentist when he instructs a patient regarding means to prevent tooth decay; the school teacher when she provides education that will cause students to take on attitudes and habits that will promote health; the health officer who recognizes that City Fathers and county supervisors must understand health problems and the means of solving them if money is to be appropriated to support public health administration. The public health engineer and the sanitarian are responsible for health education in their efforts to establish safe water and milk supplies and adequate housing for families. The public health nurse employs health education as her tool to

help mothers to seek prenatal care for themselves and preventive medical care for their children. The health educator promotes health education when he interests citizens in taking responsibility for health promotion projects. In addition, the health educator utilizes the media of publicity to make persons sensitive to health problems in order that they will seek education to solve these problems.

In a democracy, people perform as they understand. Understanding comes from participation. Everybody can learn on some level, and participate on some level. The various levels will add up to a healthy citizenry. This summary is my understanding of health education.

MAYHEW DERRYBERRY, PH.D., F.A.P.H.A.

United States Public Health Service, Washington, D. C.

Some of the others contributing to this symposium have thoroughly described the wide variety of activities that are incorporated in a program of health education. Such a definition considers health education from the point of view of the professional worker. It is a series of things that are done to, and for, people with the purpose of improving their health information, attitudes, and behavior. Certainly any adequate answer to the question "What is health education?" must include a full recognition of these tools and techniques in the program.

In addition, however, health education may be considered from the point of view of the public or layman. As such it is the *change* that takes place in his knowledge of scientific health facts, in his attitudes toward preventive and curative health practices, and in his daily living habits as a result of his many experiences. It is the knowledge gained about microorganisms and their

role in disease from reading an article on the subject; it is the public support given a health department because of its effective work on an epidemic; it is the appreciation of a doctor's diligent medical attention in a severe illness; or it is the visit to a cancer detection clinic after attending a cancer field army meeting.

But not all the changes are so favorable. Some are negative, as for example the resistance built up to clinic attendance as a result of long waits on hard benches and little help on personal health problems, or the feeling of futility that comes from participation in a blood survey or diabetes survey when no information on the individual results is given, or the use of an onion and bacon poultice on a swollen limb on the advice of a neighbor, or the lack of confidence in a periodic medical examination when a very superficial inspection is given.

Because many of the services which

the public receives from medical and public health personnel are charged with emotional reactions of fear and anxiety, they have great potentialities for health education. If the service is rendered in a pleasant manner and meets the need of the individual *as he sees it*, favorable attitudes (positive education) will result.

Conversely, only one unsatisfactory experience is sufficient to develop resistance and distrust, which is very difficult to overcome through any edu-

cational effort (negative education).

This consumer reaction phase of health education has been emphasized because the effectiveness of strictly educational efforts is greatly enhanced when medical and public health services are rendered in a manner satisfactory to the people.

Health education then is not only the activities of the professional public health workers, but also the reactions of the people to *all* their experiences with health significance.

THOMAS D. DUBLIN, M.D., DR.P.H., F.A.P.H.A.

*Professor of Preventive Medicine, Long Island College of Medicine,
Brooklyn, N. Y.*

Progress in medicine and public health cannot be judged solely in terms of monumental scientific discoveries or of important technical advances in methods of diagnosis, treatment, and prevention of disease. It must be measured also by the speed and completeness with which available knowledge and skills are applied to the total health and medical needs of all members of society. There can be no question that ignorance, fear, superstition, and indifference create an imposing barrier between what modern society is prepared to accomplish and what is actually being done to protect and improve the health of the individual, his family, and the group as a whole.

If this barrier is to be broken down, the medical and health professions must devote even greater energies than in the past to the education of the public in the proper use of the tools which science and technology have fashioned.

Public health is turning progressively toward those health problems which can be solved only by dealing directly with the individual. Simultaneously the basis for medical care is gradually shifting from palliative and curative measures

to the socially far more valuable pursuits of prevention of illness and the maintenance of health. These changes have already broadened the horizon of health education to include a concept of health as more than the mere absence of disease but rather as a state of social, psychological, as well as biological, adjustment of each individual to his total environment. Accordingly health education must assume its proper place as a highly personal service motivating the individual toward healthy living; arousing social action to create conditions conducive to health within every community; and developing awareness and stimulating effective use of the vast health and medical resources which an enlightened society provides to meet the fundamental needs of its members.

With increasing specialization of health and medical services we have established a group of technically trained workers, and others not so well equipped, and have assigned to them the task of educating for health. In so doing we have almost forgotten that by definition the physician is the teacher and health educator of those whom he serves. Though he is no longer the sole provider

of professional care and now represents only one in ten of those engaged in health and medical services, it is still to him that the individual first turns for help and guidance. It is clearly the physician's task to direct, correlate, and supervise the work of all other workers in the health field and to aid his patients in utilizing available skills. In these relationships alone, the physician has an unparalleled opportunity, as well as an obligation, for health education.

In recent years special schools and special classes have been established to train professional health educators for their appointed tasks. At the same time we have neglected this phase of the education of the one individual through whom all health services should properly be channeled. Health education is inescapably a major function of the physician, and yet it is an activity for which he, at present, is least prepared by training and experience.

ELIZABETH G. FOX, R.N., F.A.P.H.A.

Executive Director, Visiting Nurse Association, New Haven, Conn.

Others will expound the virtues of popular health education. And, when scientifically accurate and psychologically sound, mass education assuredly has its place. Perhaps it is most effective in those areas where there is little conflict with deeply rooted patterns of living and personality needs and where the pressure of social usage is greatest—for example, in creating popular acceptance of the value of immunization. But when the going is hard, when the individual course of action is inconvenient, difficult, disagreeable, or expensive, natural inertia and emotional resistance are easily rationalized. Something more than knowledge is needed to overcome them.

Fitting general principles to one's own particular requirements and means, or to the circumstances, ways, and feelings of one's family often calls for individual instruction suited to the specific situation. The taking of insulin and arrangements for a diabetic diet is a good example, or the putting into practice of the principles of child health in the daily rearing of one's own children.

When action is called for, which is painful for emotional, social, or financial reasons, motivation becomes a

highly personal matter. Some individuals are so well balanced that they can come to terms with the situation and take action without aid. Even with these individuals, the price may be undue expenditure of emotional energy.

For many others, when the situation is fraught with known and unknown obstacles—fears, social pressures, the threat of a break in personal relationships, or wholly unconscious factors—the individual becomes driven by emotion, and reason plays little part in his reactions. In such instances a counselor is needed who understands, at least in part, the art of attentive listening and of helping the person concerned to express and accept and deal with emotions blocking action. Such counseling, when safeguarded by medical knowledge, is personal health education at its best.

Let popular health education, then, prepare the ground and sow abundant seeds. But for the painstaking cultivation, let us turn to the individual counselor. It is he or she who translates general knowledge into familiar terms related to the particular individual's personality and circumstances. It is he or she who, with friendly understanding, helps the individual to make practical

application of medical truths and to meet some of the emotional hurdles in his way.

Amidst the manifold diversities of individual lives, personal health coun-

seling by the physician or public health nurse—the ancient way of one pupil and one teacher sitting down together and talking over a live situation—surpasses all other methods.

HOWARD WHIPPLE GREEN, F.A.P.H.A.

Secretary, Cleveland Health Council, Cleveland, Ohio

The education of the public toward good health is a community program of considerable magnitude. Most decreases in the death rate resulting from improved water and milk supplies and the like have already been realized.

This means that further reductions in the death rate are dependent upon what individuals do for themselves. This in turn is dependent upon what they know, are taught, and made to desire. All available methods of health education are put to work to help influence as well as teach the thousands of individuals who make up a community.

The status of health of inhabitants of an area must be determined by careful statistical studies in order to serve as the basis of sound local health education programs.

Health education to be effective must be directed toward specific groups of individuals whose educational and intellectual levels are known. Teachers, college students, school children, patients, and the general public each present a different problem. Knowledge as to the grade of school completed by various segments of the adult population is also most helpful in planning health education programs which are within the grasp of various segments of the population.

Health education must be based upon detailed knowledge of the specific subject to be treated as, for example, diph-

theria. The fact is that if a child is immunized before his first birthday, he does not contract the disease. Since babies cannot receive health education—and if they could, could do nothing about being immunized—the individuals to reach are their fathers and mothers; and there is little use in motivating them to have their infants immunized until private physicians and public health services are ready and anxious to serve.

Health education utilizes both the written word—direct mail, posters, bill boards, newspaper and magazine articles, and so forth—and the spoken word—speeches before all sorts of groups and the radio. It puts to use exhibits which appeal to the eye and exhibits which the visitors help operate. The material is taken to the individual citizen, the expectant mother, the mother with an infant or preschool child, the schoolchild, the youth, and the adult. Men, women, and children receive health education in an active health museum, in interesting lecture courses, health institutes, and so forth.

It is not enough to teach; health education must also play upon the basic human interests, such as love for children, desire for athletic strength, and pride in continuous work without loss of days from sickness. It should set up a goal of radiant, positive, good health as contrasted with mediocre or partial well-being.

WILLIAM S. GROOM

Director of Health Education, Public Health Federation, Cincinnati, Ohio

To answer this question in four hundred words is a typical assignment for the health educator. Today he must condense the subject of cancer control into a car card. Tomorrow he is expected to tell all about tuberculosis in a two paragraph poster.

His is the task of teaching all that is useful and safe for the layman to know about that vast and complex body of knowledge called medical science. And he must accomplish this with the utmost brevity and simplicity; otherwise few will read or listen and fewer will understand and remember.

Having used the first hundred words to express his appreciation of the task in hand, he must now explain all about health education in the remaining three hundred.

In my judgment the primary purpose of health education is to disseminate authentic information and advice which the layman may employ to:

1. Promote optimal health
2. Escape preventable illness
3. Recognize certain symptoms which justify prompt investigation by a competent physician
4. Participate, as a citizen, in the organized health program of his community

Instruction of the ill in the management of their illness is without the province of the health educator. This

belongs to the physician and the nurse.

In promoting these four main objectives to the adult public, mass media must be employed and the health educator would do well to recognize the experience which commercial users have had with such media.

When an entire radio period is filled with a speech, a round table discussion, or an interview, all but a few listeners will tune into some other program. Likewise when a press "story" or other printed material is long and involved it will collect relatively few readers.
